MODERN HILL CLIMBING.

The topography of many Western cities is such that, as the corporate limits enlarge, their most populous portions include districts embodying very rugged features. At Pittsburg and at Cincinnati steep hills, or rather mountains, bordering the Ohio, have long since been absorbed by the cities named, and these are covered with a dense and growing population. This has been of late years rendered the more possible by the general introduction of the inclined railway, which makes hill climbing a luxury. A fair sample of such a railway is noted in the Duquesne Incline Plane Company's roadway at Pittsburg, Pa. In this case the object in view was to surmount the hill known as Mt. Washington, located at the mouth of the Monongahela River and directly overlooking the site of the famous stronghold whose name is given the modern enterprise. The Duquesne is the latest and most complete of

and most complete of four similar enterprises climbing the same mountain. Its was opened to the public in May, 1877, and up to September 1, 1880, had carried 500,000 passengers without injury to any one. The perpendicular height reached is 400 feet, length of incline 798 feet, rate of ascent 30½ degrees. The roadway comprises, of course, a double track, one car ascending while its fellow descends, and vice

The motive power, consisting of a double engine of 70 horse power, is located at the top of the incline, and motion is communicated to the cars by the ns of a large drum carrying steel wire ca-bles of 114 inch diameter. A supplementary or safety cable, of 11/8 inch diameter, is also in constant use. These cables are each 900 feet in length, and are capable of sustaining a perpendicular strain of 50 tons, while the actual working strain is about one-tenth that amount. The safety cable passes around a system of sheaves so arranged that should the work-ing cable part the safe-ty cable will tighten about the sheaves and bring the cars to stop. The cars, neatly and strongly built, will each seat 25 persons, and in the angle beneath them and between the upper is a space available for light freight. In the Duquesne roadway there is a 900 foot sec tion of wrought fron bridge work spanning the tracks of the "Pan The rails are of the T The rails are of the T pattern, 40 pounds to the foot, and the gauge is 5 feet, the double trackway being 20 feet wide, allowing 3 feet between the caset the passing point.

Rollers of locust and "gum" wood, located at regular distances between the rails, bear the cables in their passage above them. In operating the cars, the engineer in the "cab" at the apex of the incline has absolute control of engine and cars by means of two levers. One operates the reversing mechanism of the engines and the other starts and stops the same. A brake, operated by the engineer's foot, brings sufficient friction to bear upon the cable drum to stop its revolutions even should steam be on. This drum, it might be added, is 13 feet in diameter, with a grooved periphery, and a width of 3 feet 10 inches. The cable winds into these grooves, and the movement of engines, drum, cables, and sheaves is almost noiseless, and indicates little or no strain upon any of the machinery. Experience in this plane has shown that popular prejudice against this mode of travel has ceased, and on Sundays during the summer 6,000

passengers are carried during the day and evening, the cars ascending and descending as rapidly as filled and emptied. Ordinarily trips are made every five minutes, the trip occupying two minutes. The engines, it might be added, are 24 inch stroke and 14 inch cylinders, operating a shaft bearing a driving pinion of 30 inches diameter, gearing into the main driving wheel, which is 13 feet in diameter, 12 inch face. To operate the entire affair for nineteen hours out of the twenty-four requires the services of only five men, namely, two engineers, one conductor, one freman, and one trackman. The total cost of this incline, cars, real estate, etc., was \$47,000, and it is considered a paying enterprise by the stockholders. The single fares are 6 cents. The road enjoys a growing popularity as a means of best obtaining a beautiful and comprehensive view of the "Iron City."

M. H. Batcham.

Mr. M. H. Batcham, one of the best known and most active of the promoters of scientific agriculture in Ohio, died recently at his residence in Paines-ville. Mr. Batcham was born in Kent, England, in 1818; came to this country in 1825, and for the next twenty years resided in Rochester, N. Y. During recent years he has been prominently iden-tified with the agricultural and horticultural interests of Ohio, as Secretary of the State Board of Agriculture and as a leading member of the State Horticultural Society. He was for a number of years editor of the Genesse Farmer, after which he founded and edited for ten years the Ohio Cultivator. His have been many and valuable in the Chio Farm er, the Rural New Yorker, the American Agriculturist, and other papers of this class.

The American Institute Fair.

It is to be hoped that exhibitors at the coming fair of the American Institute will be prompt in getting their goods and machinery in piace. It is a loss to exhibitors as well as a disappointment to the public to have the fair begin, as it so often does, in a general state of unreadiness.

The Chicago Mas-

Portions of a mastodon of enormous size were discovered recently in Wicker's Park, Chicago, in excavating for a sewer. The indications are that the huge animal perished in a seriest merch or danguage, and there is hupe of the recevery of the rev of the skeleton. The curved tunks are about 7 feet long.

THE INCLINED PASSENGER RAILWAY, PITTSBURG, PA.

Scientific American.

ESTABLISHED 1845.

MUNN & CO., Editors and Proprietors.

PUBLISHED WEEKLY AT NO. 87 PARK ROW, NEW YORK.

A. E. BEACH.

TERMS FOR THE SCIENTIFIC AMERICAN.

Clabs.—One extra copy of The Scheriffe American will be supplied gratis for every cuts of five subscribers at \$8.90 each; additional copies at same proportionate rate. Postage prepaid.

Remit by postal order. Address.

MUNN & CO., 37 Park Row, New York.

To Advertisers.—The regular circulation of the Scheriffe American is now Fifty Thousand Copies weekly. For 1880 the publishers anticipate a still larger circulation.

The Scientific American Supplement

Is a distinct caper from the SCIENTIFIC ANSIDEAR. THE SUPPLEMENT is issued weekly. Every number contains 15 octave pages, uniform in size with SCIENTIFIC AMERICAN. THE SUPPLEMENT, 45.00 a year, postage paid, to subscribers. Single copies, 19 cents. Sold by all news dealers throughout the country.

Combined Raires.—The SCIENTIFIC AMERICAN and SUPPLEMENT will be sent for one year, postage free, or receipt of seen dollars. Both papers to one address or different addresses, as desired.

The safest way to remit is by duraft, postal order, or registered letter.

Address MUNN & CO., 37 Park Row, N. Y.

Scientific American Export Edition.

The SCIENTIFIC AMERICAN Export Edition is a large and splendid periodical, issued once a month. Each number contains about one hundred large quart pages, profusely illustrated, embracing: (1. Most of the plates and pages of the four proceding weekly issues of the SCIENTIFIC Commercial, trade, and pages of the four proceding weekly issues of the SCIENTIFIC Commercial, trade, and another ments of leading houses, Terms for Export Edition, 45.00 a yet another ments of leading houses, Terms for Export Edition, 45.00 a yet another ments of leading houses, Terms for Export Edition, 45.00 a yet another ments of the world. People who like to mix chiccory with their coffee should undoubtedly be allowed to do so, although, for one who knowingly uses coffee so adulterated, probably there are a dozen who do it without knowing. So, too, in regard to those who use oleomargarine instead of dairy butter, taking the former knowingly on account of its lower price, or be cause a good article of butter may not be obtainable. There are many other deteriorations, adulterations, and substitutions which are also allowable, if not even entirely barmless, provided, as between manufacturer, dealer, and consumer, there be a correct understanding as to the article dealt in, and no attempt at deception is practiced. The difficulty is that deception in some form, or at some stage, seems to be an invariable accompaniment of this kind of business. The manufacturer may not deceive the large dealer, who is supposed, equally with himself, to be an expert; from the large dealer to the retailer, and from the latter to the consumer, however, the opportunities for deception, without the commission of any fraud in the eye of the law, are wonderfully increased.

Perhaps one of the most successful of the comparatively new adulterations is that of the use of glucose, made from corn, for the adulteration of sugar and sirup supposed to be made from the sugar cane. Considerable prominence has been given to this matter on account of a trial which took place in Buffalo in July, the suit growing out of a difference as to the ownership of stock in a company which had made immense profits out of the business. Glucose, or starch sugar, is not necessarily harmful, but it has very little sweetening power. Mr. R. C. Kedzie, the president of the Michigan State Board of Health, in a recent report, gives a list of seventeen table sirups he had examined, of cose. One gallon of sirup from cane sugar is estimated to have the sweetening power of 4.17 gallons of glucose sirup. The writer concludes, however, that there is comparatively little glucose in "granulated" and "crushed" sugars, of which he had examined many samples, although he found it easily in many samples of light brown sugars. He says: tals, free from floury dust, is good evidence of the absence of glucose from commercial sugars," and adds: "In the light of a kerosene lamp. common candies, where the crystalline form is purposely avoided as far as possible, glucose is often used in large quantities."

we come to the sophistication of drugs, and all that class of made at the transmitter. articles known to our materia medica, where a single indrugs, to determine how general may be the adulteration, proceeds to set forth mainly such facts as are recorded in the current literature of the last twenty-five or thirty years, most of it coming within the published proceedings of the American Pharmaceutical Association. Previous to 1848 large importations of adulterated and inferior drugs were law to regulate such importations, and designed to exclude examiner" for the port of New York, at which most of the glass. importations had been made, had occasion, during the first ten months, "to reject about 90,000 pounds of drugs, such as rhubarb, opium, jalap, gamboge, senna, yellow bark, iodine, croton oll, sarsaparilla, etc., while from 1848 to 1857 the same examiner rejected over 900,000 pounds of unsafe, adulterated, and improper drugs and medicines." It was at once demonstrated that the law had been of great benefit, for the quantity of drugs rejected within a short time after the appointment of the examiner was much larger than a brief period later, and continued to diminish for several years. The record of drugs rejected is not now kept, but the same law is in force, although it is complained that it is not as effective as it should be, because the examiners are not always appointed solely with reference to their fitness

The National Board of Health have no remedy to recom end for the present state of things, but from the printing of their report, and the diffusion of such information as is National Government can exercise more care, or make more stringent regulations if that be necessary, to prevent importations of inferior or adulterated drugs, but what seems even more necessary than this is uniform action by the various State Legislatures to more effectually control the manufacture and the dealings in a class of goods where the detection

THE PHOTOPHONE.

nium. At the recent meeting of the American Science Association in Boston, Mr. Bell read a paper describing at length his experiments in the production and reproduction of sound by light, and the invention by Mr. Sumner Tainter and himself of an instrument for the

The influence of light upon the electric conducting power of selenium is well known. Mr. Bell found the electric resistance of same selenium cells of peculiar construction only one fifteenth as much in the light as in the dark. It occurred to him that all the audible effects obtained in the telephone by variation of the electric cur-rent by sound waves, could also be produced by variations of light acting upon selenium; and that with suitable transmitting and receiving apparatus voices might be conveyed without a wire along a line of light.

The fundamental idea on which rests the possibility of producing speech by the action of light is the conception of what Mr. Bell terms an undulatory beam of light in contradistinction to an interrupted beam; meaning by the former a beam that shines continuously, but is subject to rapid changes of intensity.

The apparatus used to give the required undulatory character to light consists of a flexible mirror of sulvered mica or thin glass. The speaker's voice is directed against the back of this mirror, as against the diaphragm of a telephone, and the light reflected from it is thereby thrown into corresponding undulations. In his experiments, chiefly with sunlight, Mr. Bell concentrates upon the diaphragm mirror a beam of light, which, after reflection, is again rendered parallel by means of another lens.

The beam proceeding from the transmitter is received at a distant station upon a parabolic reflector, in the center of which only two were less than half glucose, while most of which is a sensitive selenium cell connected in a local cirthem were more than three-quarters, and four were all glu- cuit with a battery and telephone. In a recent experiment, Mr. Bell's associate operated the transmitting instrument, which was placed on the top of the Franklin school house, in Washington, about eight hundred feet distant from the receiver, placed in a window of Mr. Bell's laboratory. Through this distance messages were distinctly conveyed by means of light. In his laboratory experiments Mr. Bell "The existence of clean, well-defined, non-coherent crys-finds that articulate speech can be transmitted and reproduced by the light of an oxyhydrogen lamp, and even by the

The rapid interruption of the beam of light by a perforated disk gives rise to musical tones, siren fashion. this apparatus silent motion produces sound, loud musical The case assumes a much graver aspect, however, when tones being emitted from the receiver when no sound is

· The importance of these investigations it is impossible now stance of adulteration or substitution may put health or life to estimate. That the photophone can practically take the in jeopardy. The National Board of Health has, therefore, place of the telephone is not likely, though it is likely to done well, in the absence of any yellow fever damage this work radical changes in military and other signaling opeyear, to devote some attention to this subject, and they have rations. The heliograph, which has proved so useful accordingly issued a pamphlet in relation thereto, embody-ing a report furnished by Mr. C. Lewis Diehl, on "Deterio-rations, Adulterations, and Substitutions of Drugs." The of an enemy or across impassable streams or other low writer, after mentioning the practical difficulties attending barriers. For rapid communication between distant explorthe collection of specific information in regard to particular ing or surveying stations, the photophone also promises to be serviceable.

Another result of Mr. Bell's researches in this connection is the discovery that many other substances are sensitive to light. He has found this property in gold, silver, platinum, iron, steel, brass, copper, zinc, lead, antimony, German silver, Jenkins' metal, Babbitt's metal, ivory, celluloid, gutta thrown on our market, but in that year Congress passed a percha, hard rubber, soft vulcanized rubber, paper, parchment, wood, mica, and silvered glass. The only substances inferior and adulterated drugs. Under this law the "special found insensible to light are carbon and thin microscopic

AN ASTRONOMICAL DISCOVERY.

Professor E. C. Pickering, director of the Harvard Obervatory, lately made a discovery which is regarded as one of the most important of the century in stellar physics. In the ordinary telescope a star appears as a point of light, brighter, but not larger than when looked at with the naked Prof. Pickering finds that, on placing a prism between the object glass and the eyepiece of his telescope, the light of a star is drawn out into a continuous band. When, however, the telescope with the prism is directed to a planetary nebula, the light is collected into a star-like point without any band, enabling the astronomer to distinguish instantly between a star and a planetary nebula. This principle has already enabled Prof. Pickering to discover several planetary nebulæ. On Thursday evening, August 26, an object was observed which presented the appearance of two starhere presented, much good may ultimately result. The like points within the band in the modified telescope. It is different from anything heretofore observed in the telescope, and is regarded as an important object for investigation.

HOW ARE THE OIL TANKS SET ON FIRE BY THE LIGHTNING !

Conducting Substances and on a New Form of Table.

Again we have to record the destructive effects of lightmore in the Production of the Electric Light. By F. and difficult and where are found in the Bradford, Pa., oil regions. On the 28th Again we have to record the destructive effects of light-port, was set on fire by electricity and burned; also four smaller tanks on the West Branch near Bradford. At one In May, 1878, Mr. Alexander Graham Bell, well known in time there was danger of a gigantic conflagration, as there connection with the telephone, announced before a scientific were some twenty large tanks not far from the burning tank society in London his belief that it would be possible to hear of the Pipe Company. By firing cannon shot into the tank a shadow by interrupting the action of light upon sele- its contents were run out and the adjacent property saved.

From all we can gather there seems to be good ground for the theory that these numerous lightning disasters in the oil regions are not generally due to direct lightning strokes upon the tanks, but rather to the occurrence of alight electrical sparks within, upon, or near the tank, whereby the trical sparks within, upon, or near the tank, whereby the lightness of the caiseon are the tank of the lightness of the caiseon are the lightness of the l explosive gas that hovers about the tank is instantly set on fire. We have in our previous remarks suggested various ways in which the fatal spark may possibly be induced, to hich suggestions the reader is referred. We have now to mention one other possible cause of th

fires, and that is the electrified rain drops.

Strong electrical effects are sometimes observed during th fall of sleet, hail, and rain, without the accompaniment of thunder or lightning. Professor Tait, in a recent lecture in Glasgow, said: "Falling rain drops are often so strongly charged with electricity as to give a spark just before they the ground."

As the development of the slightest spark in connection with an explosive mixture of air and gas will produce in-tense fire, we here perceive the remarkable possibility that some of the great oil conflagrations may have been caused by rain.

The whole subject is one of much interest to electricians, and as we have before said, we hope they will investigate the matter so as to ascertain surely the cause of these frequent disasters and discover the proper means of safety.

THE HUDSON RIVER TUNNEL.

It will be remembered that on the 21st of July last a por-tion of the structure pertaining to the temporary entrance or the Jersey side of the river, opposite New York, suddenly caved in, by which sad accident twenty lives were lost. Steps were immediately taken by the directors of the Tunnel mpany to recover the bodies of the buried workmen, repair the damages, and proceed with the tunnels under the river, of which some four hundred feet had been finished when the accident occurred. In our paper of August 7th last, we gave a diagram showing the position of the break, which was near the entrance shaft of the tunnel. The plan adopted by the engineers for the restoration was to sink a coffer dam around the damaged portion, which was also the supposed place where the unfortunate workmen were congregated when the walls fell. The earth at this place is what is termed "made ground;" it is composed of refuse filling matter of all descriptions, forming a most unstable and difficult material the central tube to facilitate removal of the excavated material that the central tube to facilitate removal of the excavated material that the central tube to facilitate removal of the excavated material tube to facilitate removal o

through which to drive a coffer dam; but it was thought that the bodies of the lost could be more quickly recovered by sinking the dam than by any other means; and, therefore, the directors ordered the attempt to be made. At a cost of nearly fifty thousand dollars, and the employment of several large gangs of men, working day and night, a coffer dam of the usual construction was made ready, and its sinking began about three weeks after the ac-But after losing nearly a month's time it was found impossible to keep the interior of the dam clear of water, which came in at the bottom, owing to the treacherous nature of the ground, faster than powerful pumps could lift it, and the effort to go down further by that means had to be abandoned.

Recourse was now had to the plan of driv-g down a caisson, which is a species of diving bell. This method is now very commonly used in sinking the foundations of bridge piers into ground below the surface of the water. A caisson as ordinarily constructed consists of a timber foundation or platform of solid timbers several feet thick, interlocked in all directions to insure strength; the under side, at the edges, is provided with strong sharp lips, which rest upon the ground and support the caisson, leaving an air chamber of about five feet in height under the platform, in which the men work. Rising from the center of the caisson is an entrance tube and air lock, through which the workmen pass and the excavated material is discharged. The deck or upper surface of the caisson is loaded by building the pier thereon; the load so built on serves to carry down the caisson as fast as the men in the air chamber below dig away the earth. The rising of water within the air chamber, where the men work, is prevented

pension bridge between New York and Brooklyn were sunk. The pier on the New York side goes down 78 feet below high water mark, and the caisson men were obliged to work for a considerable time in an atmosphere of compressed air hav-ing a pressure of 45 pounds to the square inch, although the

verage working pressure was 36 pounds.

In the present Hudson River Tunnel caisson the air cham In the present Hudson River Tunnel caisson the air chamber, instead of having an interior clear space or head room of only 5 feet, has a space of about 18 feet. The object of this is to afford room for the building of the permanent tunnel entrance within the caisson after the proper depth shall have been reached. The interior of the caisson air chamber

to be by far the highest caisson air chamber ever built. It has been alleged in some engineering quarters that this caisson is not strong enough, and its failure is predicted. On the other hand, Mr. D. C. Haskin, the president of the company and designer of the calsson, avers that its strength is ample, and his plan is stated to be fully sustained by excellent engineers.

The whole enterprise from its inception has been criticised

by certain know-all engineers, who predicted that the tunnel could never be carried under water on Mr. Haskin's plan. But he answered his critics by simply going ahead and build-ing a section of the tunnel in the most difficult place prob-

ably of any on the line of the works.

The Hudson River Tunnel is one of the grandest and mos important engineering enterprises now before the public, and those engaged in its execution deserve the highest praise for the skill they have displayed. Mr. Haskin and his coadju-tors have so far achieved a great success with their plans. The unfortunate accident has hindered them a little; but we hope soon to be able to chronicle the interesting fact that the new entrance is completed and the tunnel building again going forward with rapidity.

Referring to our diagram, the new caisson is shown as it now stands suspended by iron side rods in the upper part of the abandoned coffer dam, the side lining of which tends down to a considerable depth.

nouths of the p The two tunnels below represent the n tions of the twin tunnels already built, which tunnels will form the main lines of the railway under the Hudson River. When the caisson is fully sunk home it will occupy the position shown by the dotted lines. A single broad arched tunne will then be built within the caisson to inclose the mouths of the twin tunnels; and the single tunnel will extend thence on a proper grade to the surface of the ground in Jersey

The new caisson is now nearly ready. As soon as it is completed the nuts of the side suspension rods will be unscrewed and the caisson lowered until its bottom edges rest on the earth. The workmen will enter through the central

SCALE OF FEET AIR LOCK PIPE ARCHING

THE NEW CAISSON-HUDSON RIVER TUNNEL.

by introducing compressed air into the cham-ber. It was in this manner that the piers of the great sus-ber. It was in this manner that the piers of the great sus-ber between New York and Brooklyn were sunk. be located, and during the descent of the caisson a pressure of air will be maintained within the caisson by air pumps in the usual manner. The descent will be accomplished by digging away the earth under the caisson, and at the same time building a weight of masonry on the flat deck of the structure, around the central tube

The Superiority of American Locomotives.

Additional testimony as to the superior design and construction of American locomotives is given by Mr. R. M. Brereton, Chief Engineer of the Great Indian Peninsula Railroad. After noting the fact that under less favorable conditions of climate, road bed, steeper gradients and sharper curves, from 8,000 to 10,000 train miles greater duty has the form of a tunnel with a cylindrical roof. The caisson is 41½ feet long and 25 feet wide. The roof of the chamber is composed of strong timbers, heavily braced and filled in solidity with cement, which is carried up to a level,

obtained cannot be due to better workmanship and superior materials, because it is well known that the English mechanic in skill of hand cannot be excelled, and the very best materials are employed by our English builders, and the hours of work in both countries are nearly the same. Hence I argue that the greater duty done by the American motor is due to the better designs and the better system of working the locomotives. The American builder excels in the system of framing and counterbalancing, and in the designs of the crank, axles, etc., so that the engine may run remarkably easy and without jar around short curves, and work not only on the light roads, but also diminish the wear and tear on the solid roads, and at the same time increase the effective tractive force. The English engine is a very heavy affair, and, in running, it not only wears and tears itself very rapidly, but also the roadway, and it greatly, by its undiness and jar, fatigues the drivers and firem

Coal in Manitoba,

Notice was taken some months ago of the discovery of coal in Manitoba by the Canadian geological surveyors. Recently two barge loads of coal arrived at Winnipeg from the Souris country, the first installment from what is styled the future Pennsylvania of the Dominion. The coal was forty-three days coming down the river, and is said to b of a serviceable quality. The barges were constructed at the coal fields, out of timber made from trees felled on the spot. Much difficulty was experienced on the journey, as timber jams and other obstructions to navigation were met with, but all were overcome, and the feasibility of Souris navigation determined. It is anticipated that there will be sufficient water in the river until August in each year to float barges down. At present there is twenty feet of water in the river. Mr. Hugh Sutherland, proprietor of the mines, has expended some \$15,000 on the experiment, and now that he is satisfied of its success, will go on with the work on a much larger scale. He intends to make one trip a year, building sufficient barges to bring down all the coal needed for a year's supply.

Improvements in Modes of Travel.

At the beginning of this century a passenger—more correctly, traveler—starting from New York Monday forenoon

Providence. The fare for the trip varied from \$15 to \$18, and there was an additional outlay required of from \$5 to \$6 for board and lodging; that is, the trip took up four days of time and called for an outlay of from \$20 to \$24. After the war of 1812 there was an improvement, and the time between this city and Boston was cut down to about two days, and the cost of the journey to \$14. In 1817 the fare between New York and Philadelphia was \$10, and between New York and Albany by hoat \$7, and the average time twenty-four hours. A route was that year opened between Philadelphia and Quebec, the distance 700 miles, fare \$47, required to make the journey 103 hours. In 1826 the Boston newspapers recorded the circumstance as one worthy of special comment that New York papers had been received in that city in twenty-four hours after the date of their publication. In 1828 the time required to make the journey between these two cities had been reduced to twenty-one hours, the route being from this city to Providence by steamboat, and from thence to Boston by stage. But in winter these trips were frequently given up in consequence of stormy weather, and those who wished to avoid danger and be certain in their movements still preferred the overland route. 1832 there were two regular stage lines between this place and Boston, but competition had reduced the fare. The slow line made had reduced the fare. The slow line made the distance in about fifty-two hours, and charged for passage \$7.50, while the fast or mail line took its passengers through in about forty-five hours, and charged them \$8.50 a trip. Since then railways have brought the journey within the compass of a few hours, and it is by no means improbable that the time may yet be materially reduced.

An old millstone, five and a half feet in diameter and seven inches thick, with a central hole seven inches in diameter, was left in an English orchard many years ago. In 1813 a filbert tree sprouted from the earth at the bottom of the hole, and gradually increased in size from year to year until, in 1868, it was found that the tree had completely filled the ole, and actually lifted the stone from the ground, wearing it as a girdle about its trunk.

THE Connecticut State Board of Health has wisely decided that, in the optical tests of railway men, old employes, who cannot pass all the tests prescribed by the experts employed in the examinations, may be tested by flags and lanterns of the size and colors used by the railroads at a distance of 80 rods. Of the 1,085 persons thus far examined, 56 have

AGRICULTURAL INVENTIONS.

An improved sulky plow has been patented by Mr. Horace E. Reeves, of Fort Dodge, Ia. The object of this invention is to construct sulky plows in such a manner that the plows can be readily adjusted and controlled, will be firmly held while at work, and will yield should they strike

An improved horse hay rake of that form in which a revolving rake having teeth on opposite sides of its center is connected to an axle mounted on a set of running wheels and is provided with stop devices, which either hold the rake rigid while it is gathering the load or may be released to allow the rake to revolve and the load to be dumped, has been patented by Messrs. Isaac Q. Williams and Gustavus H. Osborn, of Goshen, Ark.

New Zealand Cast Steel.

The black heach sand, so abundant in certain New Zea land shores, is likely to prove of great industrial benefit to that rising colony. The government has lately employed a mechanic to test the ore; and although restricted to an expenditure of \$500, he has succeeded in turning out five hundredweight of excellent steel. He mixed the iron sand with an equal quantity of clay and shelly sea sand to form bricks, which, after hardening in a kiln, were broken up and smelted in an ordinary cupola furnace. The product was fine cast steel, from which some promising specimens of fine cutlery were manufactured.

IMPROVED LACE CUTTER.

Since the universal adoption of belting as a means of trans mitting power, no little attention has been paid to devising means of uniting the two extreme ends of a belt, in a man ner both efficient and easy of application. Perhaps the first thing ever used for this purpose was a thong or lacing cut fashion of lacing a shoe, from which the

Judging from the amount of lace leather annually made, it would seem that the method of lacing belts was by no means the least popular. The disadvantages of cutting these lacings with a knife are so great that many consumers prefer to buy "cut lacings," notwithstanding the fact that they are seldom just what is wanted.

idea was probably taken.

This objection is fully obviated by the use of the little tool shown in our engraving, which cuts and points lacings of any length or width as wanted and without loss of time or leather.

The construction of this lace cutter will be understood from the engraving. It is a practical and well made tool, the result

of a long experience in the manufacture of tools of this class by the inventor, who was the first to place a lace cutter upon the market.

Manufactured exclusively by Sterling Elliott, 262 Dover street, Boston, Mass.

IMPROVED HARNESS BUCKLE.

The engraving shows a harness buckle possessing several points of novelty and several advantages over buckles of the ordinary style. In point of appearance it is certainly all that could be desired, and it is very easily operated. Fig. 1 is a longitudinal section of the buckle; Fig. 2

face view, and Fig. 8 is a detail view of the tongue showing the arrangement of the spring. The free end of the tongue is circular, and fits in a recess formed in the plate, C. A finger is formed with the free end of the tongue, and when the tongue is closed, the prong passes through a hole in the head plate, C, and in the plate below it. The spring catch, F, holds the tongue closed, or prevents the prong from being accidentally disconnected from the strap or trace, which is inserted between the bar, C, and the lower bar. The catch is made of spring wire, which is bent so as to have approximately a U-shape, and is confined in a recess in the under side of the tongue, E, as shown in Fig. 8. The ends of the arms of the catch, F, enter lateral notches formed in the plate, C, on each side of the recess, in which the head of the tongue fits. To open or close the tongue, E, the spring arms of the eatch are pressed inward or toward each other, forcing the ends of the arms out of notches in the bar, C.

This buckle is very readily buckled and unbuckled, a great advantage when a horse gets

down, as it can be unbuckled when the straps and traces are drawn tight. Where the buckle is applied all of the straps are kept perfectly straight, and the stitches are not worn or strained. The buckles may be of a uniform pattern throughout the harness, giving the harness a fine appearance. The spring is placed in a cavity in the tongue, and is thoroughly protected from dust, mud, and rain.

This improved buckle was recently patented by Mr. James A. Gavitt, of Dayton, Washington Ter.

NEW DISH WASHER.

Our engraving represents a very simple and effective machine for washing dishes, recently patented by Mr. Benjamin

HOWE'S DISH WASHER

from thin tough leather, and passed alternately through holes J. Howe, of Sing Sing, N. Y. The machine is shown in From large, long panniers filled with wheat they take out a

punched in either end of the belt, very much after the perspective, with a portion broken away to show the internal handful at a time, sorting it most carefully and expeditiously.

ELLIOTT'S LACE CUTTER.

placed a curved grating which supports the dishes to be

Cups and similar articles are placed on the elevated portion above the shaft, and plates and flat dishes are placed on either side of the shaft.

The paddles are of peculiar shape, being tapered and provided with flanges or lips which strengthen them and cause them to throw more water and with greater force than they restaurants and hotels will effect a great saving both in labor

cleansed in five minutes by the use of this machine as can

be done by one operator in the usual way in an hour.

It is of great utility to private families, and its use in and in dishes. This machine can be made of any size, form or material, to hold from 50 to 1,000 dishes if desired.

Photographs by Lightning.

Mr. R. Crowe, of Liverpool, communicates to the British Journal of Photography an account of some attempts to photograph a landscape by the aid of lightning flashes. A gelatine plate, requiring by day an exposure of two seconds, was exposed from 10:15 P.M., to 10:45 P.M., during which time there were 120 brilliant flashes and about half as many minor ones. Most of these were in a horizontal direction, and five or six of them were imprinted on the negative. A perpendicular flash which struck a church tower half a mile away was rendered with extraordinary sharpness and brilliancy. The surrounding objects, in spite of the long exposure, were but feebly impressed; whence Mr. Crowe argues that though the light of a flash of lightning is of a very actinic character, there still is not sufficient volume of light to illuminate a landscape or building to allow a successful photograph to be taken. [The probable difficulty is that the photo-plates are not sufficiently sensitive. The duration of a lightning flash was found by Wheatstone to be less than a millionth part of a second. We believe there is no record of the successful photographing of any object with a plate exposure of so short a length of time, even in the strongest sunlight. - EDs.]

Bread Making in Spain.

The bread in the south of Spain is delicious; it is white as snow, close as cake, and yet very light; the flour is most admirable, for the wheat is good and pure, and the bread well kneaded. The way they make this bread is as follows:

and throwing every defective grain into another basket. This done, the wheat is ground between two circular stones, as it was ground in Egypt two thousand years ago, the requisite rotary motion being given by a blindfolded mule, which paces around and around with untiring patience, a bell being attached to his neck, which, as long as he is in movement, tinkles on; and when it stops he is urged to his duty by the shout of "arra mula" from some one within hearing. When ground, the wheat is sifted through three sieves, the last of these being so fine that only the pure flour can pass through it; this is of a pale apricot color. The bread is made in the evening. It is mixed with sufficient water, with a little salt in it, to make into dough;

construction. A shaft carrying paddles revolves in a suit. a very small quantity of leaven or yeast in one batch of able vessel of tin or galvanized iron, and over the shaft is household bread, as in Spain, would last a week for the six or eight donkey loads of bread they send every day from their oven. The dough made, it is put into sacks and carried on the donkeys' backs to the oven in the center of the village, to bake it immediately after kneading. On arriving there the dough is divided into portions weighing three pounds each. Two long, narrow wooden tables on trestles are then placed down in the room, and a curious sight may be seen. About twenty men, bakers, come in and range would if made perfectly plain. The vessel containing the themselves on one side of the table. A lump of dough is dishes and the paddle shaft has a tight-fitting cover, and handed to the nearest, which he begins kneading and knock-

ing about with all his might for about three or four minutes; and then passes it on to his neighbor, who does the same, and so on successively until all have kneaded it, when it becomes as soft as new putty and ready for the oven. Of course, as soon as the first baker has handed the first lump to his neighbor, another lump is given to him, and so on until the whole quantity of dough is kneaded by them all. The bakers' wives and daughters shape the loaves for the oven, and some of them are very small. They are baked im-

si si ki in ta re

mediately. Electricity on the Stage. In Paris, during the play of " Le Pied de

Mouten," a table is brought on to the stage, and afterwards a candlestick carrying two lighted candles. One of the characters in the play blows out the candles; but as soon as he moves away one of them unaccountably becomes relighted. The actor again blows out this light, when the other one becomes kindled; and, becoming enraged, the man takes up the candlestick and blows furiously without being able to extinguish the lights This effect, which gives rise to some amuse-

ment and astonishment, is produced by means of an induction spark which inflames the vapor from a mixture of ether and spirits of turpentine contained within the vessels which

A cable of four fine conductors connected the latter, washed, with the expenditure of very little labor, and the and the points between which the spark passed, with breakage and nicking of dishes is entirely avoided. It is the table, and through it with the induction coil below the

GAVITT'S HARNESS BUCKLE.

the shaft is provided with a crank by which it is turned. permanently. The vessel is partly filled with water, with the addition of a little soap, and the crank is vigorously turned both ways for a moment or so, when the cover of the vessel is removed and a quantity of water is poured over the dishes to represent the wax tapers. The dishes are quickly and thoroughly claimed that as many dishes can be washed and thoroughly stage.

A NEW ROCK DRILL.

The skill of a great many able mechanics and engineers, and a great deal of capital, have been employed in simplify ing and perfecting machinery for drilling purposes, the principal object being to avoid breakages, which are far too com-mon in the ordinary machines. It has been found by actual observation that where any great amount of work is being done it requires six drills to accomplish what should be done by four on account of the loss of time occupied in repairing broken parts.

In former machines the parts most liable to breakage were the valves, and as no modification of their construction has been sufficient to give them a durability which compares with that of other parts of the engine, the difficulty in many cases seems wholly irremediable, and the only recourse is to have a sufficient supply of duplicate parts on hand to be ready for emergencies.

Notwithstanding the many failures, mechanics and engineers, appreciating the immense benefits to be derived in

the line of experiment naturally tended in the direction of valveless engines. These were known to be perfectly practicable in some respects, while in others, more particularly in the displacement of the compressed air or steam at the ends of the cylinder at the termination of the stroke, and giving a cushion for the piston to prevent severe concussion with the cylinder heads, the problem has re-mained unsolved until now.

Mr. S. G. Bryer, of Saugus, Mass., who has had an experience connected with rock drills of over ten years, after much experiment has devised the only thoroughly practicable valve-

less engine for a rock drill yet made. The piston of this drill is its own valve, thereby dispensing with the small valves and their consequent wear and breakage, together with many other small and weak parts common to other drills. As will be seen by reference to the engraving, it has fewer parts than any other rock drill in the market. Practically, there is nothing but the cylinder, the piston, and the rotating motion, which is perfectly simple and scarcely exposed to wear or breakage. The blow delivered is as positive and effectual as that from any other style of drill—a result which has never before been obtained with a valveless

The advantages of this drill consists in such an arrangement of parts as to entirely obviate the use of tappets, valves, or other auxiliaries depending for their action upon percussion; while it is a perfectly effective and smoothly-working machine, free from liability to accident. It is sought to reduce it to the smallest number of unexposed parts, and so to simplify them that they can be easily repaired or duplicated and be interchangeable.

In the upper portion of the sectional cut, midway between the center and either end of the cylinder, are two annular

grooves; these are connected on the back by a passage way, forming a steam chest, to which the supply pipe is attached. The exhaust port is located in the center of the cylinder. In the piston head are two grooves, which also pass entirely around, corresponding in width to those in the cylinder, distant from each other half the space of the latter from the exhaust port. In the right-hand portion of the piston, extending from the grooves in the same to either end, is shown a passage way for steam. In the lower part of the cut is what is termed the cushion valve, its lower end resting upon the lower head of the valve chamber. valve is cylindrical, and reduced in size, between the ends and middle, to admit of free passage of steam to the exhaust ports of its chamber.
From this description, the operation of

the drill can be easily understood. steam forms a cushion at the end of each stroke, which prevents the piston from knocking. To the upper head of the cyl-inder is secured the usual device for rotating the piston and drill, consisting of a rod with spiral flutes, entering a socket in the piston head.

The improvements embodied in this drill secure a large percentage of useful effect, with the least supply of steam, the utmost expansive power of the same being utilized by its peculiar construction; and since no part strikes another to give it motion, the wear is insignificant. The inventor has displayed great skill in locating the control of the piston's action within itself, thus rendering the free and perfect operation of the drill whelly independent of auxiliary appliances. The drill may be operated equally well by the use of compressed air, and is absolutely non-freezing. In our opinion she claim of the manufacturer that this drill presents the greatest simplicity and efficiency is

well founded; and we think that wherever it may be intro-duced, it will give satisfaction. Mr. J. Allston Newhall, 67 duced, it will give satisfaction. High street, Boston, Mass., is the proprietor and manufact turer.

NEW INVENTIONS.

An improvement in whiffletrees has been patented by Mr. Ferdinand O. Fischer, of Aptos, Cal. The invention consists in combining a lever spring, shouldered bar, and slide bar having end disk, with the end of a whiffletree.

Mr. John Flanagan, of Newburg, N. Y., has patented a hydrant formed of a case with waste opening, shouldered valve rod, fluted screw plug valve, and a ring. The arrangement of the several parts cannot be described without an engraving.

Messrs. Carl P. Cullmann, of Idar, and Carl A. Lorenz of Oberstein, Germany, have patented a process of manufac turing onyx stones from agate, by immersing one side in a bath of dilute nitric acid and iron, the other side in a bath of success, have pluckily continued with their experi-as valves could not be made sufficiently durable, stove, and burning them to fix the color.

Fig. 2.-LONGITUDINAL SECTION OF ROCK DRILL.

Mr. Carl J. Renz, of Hudson, N. Y., has patented an im- regularly perusing it. proved process of preserving fruits, and more particularly grapes, pears, strawberries, and other fresh whole fruits without the use of a mother liquor. It is an improvement in that general process of preserving in which the air is first exhausted from the receptacle in which the fruit is placed, and in which the gases subsequently evolved by the fruit are taken up by an absorbent. The improvement consists in de-odorizing and absorbing the condensable gases by a block of quassia wood or other material impregnated with qui

A simple and efficient apparatus for obtaining a vacuum has been patented by Mr. Lyman H. Ward, of St. Mary's, Texas. The vacuum is formed in this apparatus by the dis-placement of water or other liquid.

Origin of Fires.

Theories of fire "origins" run in fashions, and at times, the American Exchange and Review thinks, the favorite presumptions become much overdone. Defective flue is the actual source of a great many ignitions, and it is not apt to

Fig. 1.-THE BRYER ROCK DRILL.

sionally we may go too much on "defective flue." A clothes press adjoining a flue in a Pittsburg dwelling lately took fire; defective flue was, of course, named as the flame maker. but, on further examination, it was found that the closet was a receptacle for soiled clothes and rags, and some the latter were saturated with an oleaginous lotion for 'rheumstiz." The combined oil and cotton, in a confined atmosphere, at a temperature produced by the heat radia-tions from the flue, were together inflammable. The "mishap" will perhaps go by the name of spontaneous combus-tion, yet this is solely due to the fact that the substance required a comparatively low temperature in order to ignite: flue was the inciting cause, so far as relates to the merely physical condition of the fire-making. Fires are generally of mixed origins.

erican Manufactures by a Colonial Editor.

The last issue of the Victoria Review, the leading maga zine published in Australia, pays the following tribute to American manufactures and to our series of illustrated articles on American industries. American manufactures, says

the editor, are a perpetual source of wonder and of instruction to the foreign observer. In perfection of machinery, scientific division of labor, and completeness of execution, there is nothing in the world besides to be compared with them. To visit the great continent and inspect the leading manufactories must be equal to a good education for any sing a mechanical turn of mind. But, failing time and means to go forth on such an expedition, a foreign reader can make himself as well acquainted with the subject as if he were on the spot, simply by taking in the Scientific American and

In the current numbers there are full descriptions, illustrated by excellent woodcuts, of the manufacture of printer's types by Messrs. Farmer, Little & Co., of New York; the manufacture of Mége eleomargarine and eleomargarine butter by a New York company; the brass manufacture of the Benedict and Burnham Company at Waterbury, Conn.; and of the great tunnel under the Hud-son River, between New York and New Jersey, which is of a similar character to the London underground railway, and is in the hands of a company holding a capital of \$10,000,000. The tunnel will be 5,000 feet long, or more than three times the length of the Thames tunnel. There seems to be but little doubt of its being carried through to completion.

The eleomargarine butter is a product extracted from beef fat, according to a principle discovered by M. Mége, a French chemist, about twelve years ago. The butter produced is pure, perfectly wholesome, and suitable for all domestic purposes. The company work up an average of 100,000 lb. of fresh caul fat daily, producing from 40,000 to 50,000 lb. of butter, selling at from 15 to 20 cents a pound. This invention of the French chemist has added many mil-

> before us, a vast variety of illustrated descriptions of new inventions and improvements in many branches of mechanical construction. It was shrewdly obnical construction. It was shrewdly ob-served by the English Consul at New Orleans, in a report he lately sent to the British Government, that the superiority of American over British manufactures due, among other things, to the fact that the Americans never raise the objection to any novel "notion" or suggestion that it is "new-fangled." In fact, they rather prefer it on that account. The newer, the more likely to be an improvement on the old method, is the principle they go by. English manufacturers, on the other hand, proceed on the most rigid lines of custom and precedent, and are very jealous of anything in the shape of an innovation on the established methods. The result of this difference between the two nations is that the Americans are beating the British completely out of the field in many branches of manufacturing industry. Edison's "new-fangled" inventions are not alone revolutionizing the world of practical ideas, but are making their inventor rich beyond the dreams of avarice. It is to the Americans, rather than to their home friends, that Australian manufacturers should turn their eyes for prece dents and examples. The SCIENTIFIC AMERICAN ought to secure a wide circulation in this part of the world. To manufacturers of every description it is sim ply invaluable.

MECHANICAL INVENTIONS.

Mr. Perry A. Peer, of Comstock, Mich., has patented a hinge peculiarly adapted to a V-shaped harrow. When it is de-sired to uncouple the two sections of the harrow, one of the sections is allowed to lie flat on the ground, and the other is raised to about a vertical position, and it may then be readily detached.

Mr. John O. Grisham, of State Line, Misa, has patented a corn cutting and grinding mill, which is an improvement upon the form of corn crusher in which the ears of corn in the husk are fed through throats, sliced into sections by revolving knives, and these sections then rendered fine by passage between grinding surfaces. The invention consists in combining with the feeding throats and knives, a set of spring seated tables, which hold the ends of the ears of corn while being cut, and which allow the sections being cut off to press down to accommodate the thickness of the knife, thus preventing the knife from hanging in the ear, and rendering the cutting action easier.

Mr. Isaac S. Schuyler, of Brooklyn, N. Y., has patented a machine for cutting screw threads. The improvements relate to machines for cutting screw threads on pipes and couplings, internally and externally, and are designed to accomplish such work more rapidly and perfectly than has heretofore been done. Rotary cutters formed with serrated edges are employed. The arbors of the cutters are fitted in a revolving head that has an endwise motion proportioned to the pitch of the screw, so that while the cutters rapidly zevolve with their arbors they also travel in a spiral path upon the surface being operated upon.

Mr. Charles G. Trafton, of Slatersville, R. I., has patented a thread guide for spooling machines that is self-adjusting to the yarn as the latter runs from the bobbin to the larger spool, so as to avoid friction. It consists in a guide plate provided at one end with a curved friction surface and at the other with a slotted flange and a plate, in combination with a rod having projections at its top to limit the move ments of the plate sidewise and a screw which serves as a pivot for the plate.

An improved gin saw sharpener has peen patented by Mr. Robert S. Mudford, of Texarkana, Ark. The object of this invention is to improve the construction of the gin saw sharpeners for which Letters Patent No. 20,933 were granted to A. H. Burdin, July 20, 1858, in such a manner that they will bring the teeth to a better condition.

Mr. James H. H. Taylor, of Lawrence, Mass., has patented a mechanism for stopping and starting street cars, so constructed that the momentum of the car can be used for stopping the car, stored up, and again used for starting the car.

Mr. William W. Rochelle, of Star Landing, Miss., has patented a tool for sharpening the teeth of cotton gin saws. It is made in three pieces—the sharpening bit proper, which is shaped at its outer end to enter between the teeth, the head or shank, which is formed to receive and support the bit, and a sliding collar, which clamps the bit in the head by a wedging action.

DECISIONS RELATING TO PATENTS. By the Commissioner of Patents.

STEVENS 09. PUTNAM.—INTERFERENCE.—WIRE BARBING

Machine.
Marble, Commissioner:

 The earliest date at which an invention can be said to exist is that time when there was in the mind of the inventor a well defined idea of something which might rightfully constitute the subject of a patent.

2. The law is well settled that a mere unembodied principle or discovery is not a subject of a patent, and it must follow that the mere mental apprehension of the same is not the conception of an invention. When, however, the principle or discovery is rendered of practical service by its embodiment in material form, there exists something for which a patent can be allowed, and the union in the mind of the inventor of the principle or discovery with the means of its embodiment is conception of the invention.

8. A combination, as distinguished from a mere aggregation, may be defined as a union of elemental parts co-operating dependently to produce a desired result, and a conception of such combination must include not only the idea of associating the parts, but also that of so uniting them that there will be a dependent co-operation.

4. The fact of the conception of an invention is one which public policy demands shall have been so evidenced as to be capable of other proof than the mere allegation of the inventor that such invention was at a certain time in his mind before it can avail bim anything, and so long, therefore, as he keeps his invention unembodied and undisclosed it cannot serve to antedate and thus defeat the invention of a contestant.

United States Circuit Court.—Southern District of New York.

BRICKILL of al. 00, THE CITY OF NEW YORK.—PEED-WATER
HEATERS FOR STEAM FIRE ENGINES.

Wheeler, J.:

1. Letters patent No. 81,169, granted August 18, 1868, to William A. Brickill, for an improvement in feed-water heaters for steam fire engines construed and sustained.

2. Section 7 of the act of 1830, which provides that every person or corporation may use and vend to others to be used any specific machine, manufacture, or composition of matter which they have purchased or constructed prior to the application for a patent, applies in cases of patents for substantive things to the particular things so purchased or constructed only, and does not include the right to practice the invention without liability.

3. The patent involved in the case of McClurg vs. Kingsland was for a method of casting iron rollers, and it is not probable that the decision rendered in that case would be followed beyond cases of the same statutory class.

Scientific American.

4. By the act of 1870 the right of a person constructing or purchasing a patentable article before the application for a patent is limited to the right to use or vend the specific thing, and this, whether it be regarded as a legislative construction of the former acts or not, may properly govern the right of recovery in actions brought since its passage.

For an infringement of a patent by its fire dapartment a city is liable.

U. S. Circuit Court—Northern District of Illinois. WASHBURN & MOEN MANUFACTURING COMPANY 28. HAISH. —BARBED FENCE WIRE.

Blodgett, J.:

 A person has no right to mark his goods with any words or terms indicating that they are manufactured under a patent which he does not own and has no right to use.

A defendant, having so marked his goods, will not be allowed to defend himself by denying the validity of such patent.

Complaints about the Patent Laws.

There is a growing disposition in some branches of industry in this country to find fault with our patent laws and the manner in which they are enforced. There is hardly a trade that has not at frequent periods its crop of harassing patent suits, which perplex the manufacturer, the dealer, and the consumer. It is not surprising, therefore, that the dissatisfaction thus created finds expression in complaints. Naturally, the subject comes up before the asso formed among those belonging to the various trades for their mutual protection and the advancement of common interests. A committee is appointed, and, if its members are in earnest, a report is drawn up suggesting possible measures of reform. Such has been the course pursued by the millers, and we learn that the brewers have taken the first steps in that direction. All this is very well in its way, but it does not seem as though the agitation of the subject is conducted in the manner best calculated to secure the reforms desired. The reports of such committees are so evidently biased by the interests of the members, as defendants in patent suits, as to have, as the rule, little or no value. The one great and sole object of their efforts seems to be to beat the particular patent or patents which menace them, and the fact is lost sight of that it is to the interest of every enterprising manufacturer to aid in sustaining patents. In many cases where complaint against the patent system is loudest, known rights have been infringed, and the protests of patentees disregarded, in the belief that it was cheaper to take the chances of infringing than to recognize the demands of those whose claims were disregarded. Patents thus ignored almost always acquire an unexpected value before they expire, and it is quite usual for them to be made the basis of expensive suits. Often they are sustained by the courts and become very valuable, for the simple reason that they have been infringed without regard to consequences. Manufacturers who find themselves figuring as defendants in suits of this character commonly have a great deal to say about the injustice of our patent laws. Perhaps they are unjust in their requirements in some instances, but to modify them in any essential particular in points touching the value of valid patents would be to destroy an immense property right, and to make it extremely difficult for an inventor or the owner of a patent acquired by purchase to protect himself in the enjoyment of the rights it is designed to secure to him. It may be vexatious to settle or defend frequent demands for royalties and damages; but it is still more so to know that you have valuable rights in patents which you are unable to enforce, and that which should belong to you

alone has become common property.

The only safe and honorable position for the manufacturer is one of justice and fair dealing. He should act advis-edly with regard to the payment of royalties and the infringement of patents. If he manifests a fair and liberal disposition in this matter, and a willingness to recognize the rights of others as beginning where his own rights cease, he is not likely to have serious trouble. As the rule, it is cheaper to purchase a right under a patent than to defend an infringement; but when a manufacturer persistently disregards notices and warnings, and takes his chances as an infringer, be should stand by the conse-quences like a man, and not whine nor complain if called upon to pay for what he has taken without leave. He may, at least, have the satisfaction of knowing, under such circumstances, that every decision of the courts affirming the validity of patents increases the value of those he owns and controls, and that he has thus a direct interest in sustaining all good patents. But then we must make some allowance for human nature, and it certainly does make a great difference in a man's feelings whether he appears as plaintiff or defendant in a patent suit. He often does and says a great many things when he is defending an infringement suit which be would be very sorry to have quoted against him should be ever find it necessary to move for the protection of his own rights and interests. Our patent laws may be susceptible of improvement, but the men to improve them are not found on committees representing cliques of defendants interested in suits brought to recover damages for the wholesale infringement of valid patents. What they have to-say may always be taken with some allowance.-Iron Age.

Apples for Foreign Markets.

Speaking of the magnificent apples shipped from the United States, the London Magazine of Pharmacy says that there is no reason why this splendid fruit should not be received in London as fresh and blooming as when first gathered from the tree. To secure this most desirable result each apple should be wrapped in soft tissue paper, previously soaked in a solution of salicylic acid and dried.

The best preparation of salicylic acid for this purpose is the alcoholic solution, made with the strongest spirit, and then diluted with as much water as it will bear without precipitating the acid, so as to make the solution go as far as possible. Each apple should be enveloped in at least three or four folds of salicylated paper, and every possible precaution should be taken to prevent bruising when loading into the casks or cases. Well-packed apples should not move at all during the voyage, and the shaking of a railroad train should have little effect upon them. Nevertheless, a certain amount of contusion is inevitable, and to avoid the ulterior results of this, the salicylated paper is indispensable. As to the cost, it would be a mere trifle when we consider the result gained, and the splendid condition of the fruit when it would enter the London market. Besides, it is very probable that the salicylic acid paper used for packing the apples in America might be used over again, or applied in England to some similar antiseptic purpose, and an allowance made for it accordingly.

Prehistorie Mexico.

Very interesting discoveries have been made by M. Desire Charnay in ancient cemeteries high up on the slopes of the velcanoes Popocatapetl and Itztaccihuatl. The burial place on the latter mountain is high above the line of vegetation. Just below it is a small valley almost concealed on three sides by a natural bulwark of stupendous rocks.

Access to this singular dell seemed at first impossible; in fact, was so difficult as to lead M. Charnay to doubt the tradition of a Chichimecan village having existed in such a place. Excavations have led to the supposition that this narrow valley had been a temporary refuge of the Toltecs, perhaps as early as the year 600. It bore evidence too of having been inhabited by the Chichimeca Indians. Idols and household utensils similar to those found in ruined Chichimecan villages were dug up from a depth of from three to four feet. Singularly, too, there were found near the surface Aztec relics, which proved that at a comparatively recent date this natural stronghold had served as a place of concealment for a third tribe. Tradition says that after the Spanish conquest in 1520 a few spirited Aztecs and Tlatelolcos, rather than submit to slavery or accept the doctrines of the invaders, fled with their "lares and penates" to this mountain fastness and subsisted on corn, frijoles, and other vegetables, burying their dead as near the "snow line" as possible. Many Aztec idols, vases, and jars were un-

Pacific Coast Fishes.

The United States Fish Commission have obtained on the Pacific coast 270 species of fish. Among these are nineteen species of sharks. Two large toothed man-enter sharks, caught in Monterey Bay, measured from 28 to 24 feet in length, and weighed fully two tons each. Another variety of shark found on the coast averages 32 to 38 feet in length, and weighs three tons. Their teeth are small, and they are not dangerous. Monterey is a middle ground where the fishes from north and south meet, and no locality on the Atlantic coast is so rich in species. It has about 130 species; San Francisco about the same; Santa Barbara, 95; San Diego, 90; and Puget Sound, 90. The so-called perch, found on the California coast, are not true perch. A million and a half of salmon, averaging from 25 to 30 pounds each, are taken from the Columbia River, and from seven to eight millions of pounds of fish are taken from San Francisco Bay and marketed.

Monument to the Original Promoters of the Union Pacific Railway.

Norcross Bros, of Chicago, have contracted with the Union Pacific Railway Company for a monument to the memory of Oliver and Oakes Ames. The monument is to be located at Shannon, Wyoming Territory, at a point about 400 miles west of Omaha. It is at the highest point in the Rocky Mountains which is crossed by the railroad. The monument is to be 50 feet square at the base, and 60 feet high, pyramidical in outline, with three slopes. The material will be Black Hills granite. There are to be two medallions representing the heads of Oliver and Oakes Ames in alto-rilievo. One will face the east and the other the west, at a height of 40 feet from the ground. On the side next to the railroad will be an inscription, "In Memory of Oliver and Oakes Ames." The medallions are to be cut out of McGregory quarry brown stone. There is also to be a bronze tablet, which will more particularly show why the monument was erected. The contractors are to complete the work in about two years. The cost is to be about \$80,000.

An accidental dropping of a cipher in our recent description of the heavy Worthington oil pumping engines leads to an obvious understatement of their efficiency. The work actually done by some of these pumps is the pumping of 15,000 barrels of oil through 100 miles of pipe, against the enormous pressure of 1,500 pounds per square inch.

RECENT INVENTIONS

Mr. George Steinson, of East Chester, N. Y., has patented an improved leg for bedstead frames, which furnishes to the bed an elastic support. The leg is formed of flat curved springs, and a spiral spring placed in a box, the whole being supported on casters.

Mr. Fredrick A. Baker, of Brooklyn, N. Y., has patented

a fire escape ladder for the use of firemen. It can be readily secured to the windows of buildings from story to story to form a fire escap

An improved legging, which fits closely to the foot and

an improved legging, which his closely to the foot and ankle, and can be opened or closed easily, has been patented by Mr. Casper Riese, of Berlin, Prussia, Germany.

Improvements in electric burglar alarm for safes have been patented by Mr. Edwin J. Leland, of Worcester, Mass. These improvements relate to burglar alarm telegraphs con nected with safes, vaults, and similar places, and arranged to give a signal at a central office in case the circuit is broken or the wires tampered with. Such lines usually have com-bined with them a galvanometer, so that any change of resistance caused by an attempt to put a loop in the line, and thereby cut out a safe or vault without breaking circuit, or from any cause, shall be indicated by the galvanometer. The object of this invention is to provide means for testing the line at any time and determining whether the safe or vault is is circuit, so that it will not be necessary to make a personal inspection of the vault or safe every time the indicator shows a change of resistance or the signal is operated, as such effects are often produced by crossed wires and electrical disturbances in the atmosphere.

An improved bottle stopper has been patented by Mr. Thomas G. Austen, of Oswego, N. Y. This invention relates to that class of devices that are designed so close the uth of a bottle and yet to permit the gradual ejection or sprinkling of its contents.

Mr. Joseph T. Maybury, of Mobile, Ala., has patented a process of canning oysters, which consists in placing them in cans and pouring over them a hot mixture composed of water, salicylic acid, and vinegar, in the proportions of about llons, one and six-tenths gill, and one-half gallon, respectively, and then closing the cans and placing them in A novel skylight bar, in which provision is made for col-

lecting the condensed moisture which accumulates on the interior surface of the glass and conducting it to the roof, has been patented by Mr. Fred Ruemping, of Kansas City,

An improved well casing, which is simple and effective, has been patented by Mesars. Henry Shear and Henry M. in the *Electrician*: Toomey, of Arcola, Ill. The invention consists in a well and cistern casing formed of a number of segmental sections of earthenware or burned clay, provided with tongues and grooves at the ends and with strengthening ribs on the inner

Messes. William P. Lyon and Samuel Vail, of Port Chester, N. Y., have patented a fastening for the end boards of wagons and carts, so constructed that it will fasten auto-matically when the end board is raised into place, and which, when locked, will hold the end board securely.

Mr. John H. Reed, of Cowles, Neb., has patented a new penmanship-instructing chart, which will permit persons who are not good penmen themselves to instruct others in the art of penmanship and to explain the proper formation and inclination of letters.

An improved trunk fastener, patented by Mr. George A. ofield, of Jersey City, N. J., consists in the combination with a bolt tongue having a transverse groove of a socket provided with a longitudinal groove to receive the bolt, and with a transverse groove containing a spring latch fitting into it and catching into the transverse groove of the bolt

Mr. Patrick H. Duke, of Richmond, Va., has patented a package of plug tobacco having the faces of its plugs formed into perfect squares, one set of which is raised and the alternate set depressed, with the raised and sunken faces of one layer or set of plugs fitting into and over the sunken and raised faces of the crossed piled plugs forming the next layer.

An improved apparatus for distributing fertilizer, which may be made either an attachment of an ordinary seeder or ier, or used independently thereof, has been patented by

Mr. Luther A. Horine, of Jefferson, Md. Mr. Carey Inskeep, of Ottumwa, Ia., has patented an improved hairpin, which is so constructed that it cannot become detached accidentally, but may be inserted and removed without disturbing the contiguous hair further than requisite to allow space for the body of the pin.

Mr. Edward A. Smith, of Greeley, Col., has patented an approved earth auger, which consists in a novel arrangement

of the casing, the cutter, and the drill point in a well auger.

Mr. Benjamin Le Coultre, of Geneva, Switzerland, has patented a chronograph having both second and minute hands indicating by one dial and mounted on the same arbor. The inventor fits upon the central arbor of the watch a loose eleeve that carries the minute hand and a driving wheel, and outside of this fits a second loose sleeve carrying the second hand and a driving wheel. Upon a lever fitted for movement by a ratchet wheel in the usual manner are fitted the wheels that operate the second hand from the center pinion when moved into gear, and upon a pivoted arm that is connected with the lever is a pinion that connects a fixed pinion on the center arbor with the driving wheel of the minute hand. than in the neighborhood of the cathedral.

The driving wheels of both the second and minute hands are fitted with heart cams that are acted upon by a T-arm to bring both hands back to the starting point. By this con-struction a simultaneous action is obtained on both hands first, to set them in motion; second, to arrest them; and, third, to return them to the starting point.

Welding by Pressure.

Pursuing his researches on the welding of solid bodies by ressure, M. Spring has subjected to various strong pressures (up to 10,000 atmospheres—150,000 lb. per square inch) more than eighty solid pulverized bodies; this was done in vacuo, and in some cases at various temperatures. The results are highly interesting. All the crystalline bodies proved capable of welding, and in the case of bodies accidentally amorphous the compressed block showed crystalline fracture; crystallization had been brought about by pressure. Softness favors the approximation of the partiaxes. The amorphous bodies, properly so called, fall into two groups, one of substances like wax (circid bodies), which weld easily, the other of substances like amorphous carbon (aciroid bodies), which do not weld. The general result is that the crystalline state favors the union of solid bodies, but the amorphous state does not always hinder it. M. Spring says the facts described do not essentially differ e observed when two drops of a liquid meet and ucite. Hardness is a relative, and one may even say subjective term. Water may appear with a certain hardness to some insects, and if our bodies had a certain weight we ould find the pavement too soft to bear us. Again, prismatic sulphur is changed by compression to octahedric sulphur; amorphous phosphorus seems to be changed to me tallac; other amorphous bodies change their state, and mix-tures of bodies react chemically if the specific volume of the product of the reaction is smaller than the sum of specific volumes of the reacting bodies. In all cases the body is changed into a denser variety, whence may be inferred that the state taken by matter is in relation to the volume it is obliged to occupy under action of external forces. This (M. Spring points out) is merely the generalization of a well known fact. Some curious results are deduced from it. The researches described have important bearings on mineralogy and geology.

A MODIFIED DANIELL CELL.

Mr. S. J. Browning, of Portsmouth, England, has devised modified form of Daniell cell, which he thus describes

"While using the same materials, and the of solutions as those of the ordinary Daniell, it gives twice the amount of current.

"It can be clearly perceived that my main object has been the reduction of the internal resistance, which I believe I have accomplished to the utmost without reducing its con

ompanying diagrams illustrate this cell: 1. Outer copper cylinder. 3. Inner copper cylinder, which encirc the porous cell within one-eighth of an inch of same. 3. The copper shelf surrounding No. 3, for holding sulphate of copper. 4. A wooden cylinder with step turned inside, to keep porous cell in center of No. 2, and with three wooden plugs, to keep No. 2 in center of No. 1. 5. Ordinary eight inch porous cell. 6. Cylinder of zinc.

Mr. Browning uses small blocks of vulcanized India rubber to keep the zinc in the center of the porous jar, and again to keep the porous jar in the center of the cylinder. He also uses a disk of felt for the zinc to rest upon.

High Lighting by Electricity.

There was very little to encourage the project to illuminate Holyoke, Mass., by means of lofty electric light towers in the result of the similar experiment tried in Rouen, France during the files of July 18 and 14. On that occasion eight electric lights were placed on the spire of the cathedral with a view of illuminating the town. Though the quantity of light was estimated at 5,000 Carcel burners, the effect was practically nii. The spire seemed merely to have a huge lamp on it, which threw its light beyond the town rather

A New Process of Befining Petroleum

The Philadelphia Record says that a new pro ing the products of petroleum is being tested in that city. At present all oils are brought to heat tests by distillation, and in the process lose from 30 to 65 per cent. By the old process oil at a fire test of 110° costs 6½ cents per gallon. In bringing this grade of oil to a test of 150° it loses 30 per cent in the process of distillation; to raise it to 175° it loses 45 per cent, and to 185° 65 per cent. By the new patent process the oil is treated without best and loses pathing. ss the oil is treated without heat and loses nothing.

Oil at 110° that cost 6½ cents per gallon, on being raised to a fire test of 150 is worth 18½ cents per gallon; to 175, from 15 cents to 17 cents per gallon, and if raised to 185° is worth from 18 to 20 cents per gallon. The cost of raising it to any of these tests is 1 cent per gallon. Here, also, is another advantage over the old system, as by the present method of distillation the profit on oil at a fire test of 110 is only half a cent per gallon, and at a test of 150 the profit is the same, whereas by the new process, the oil losing nothing in the manipulation, the profit is in a ratio to the number of de-grees to which the fire test is raised. In the process the oil is deodorized, and at the same time the illuminating quality is improved so that the oil burns longer and brighter, and this is effected without the aid of any heat whatever. is what the inventors claim for the new process, but until a rigid and satisfactory test has been made they will disclose neither their plans nor their names.

Eruption of Fuego.

A letter from San José de Guatemala, dated the 2d of July, to the Panama Star and Herald, says: " At 3 A.M. on the 29th of June, the volcano Fuego suddenly became active, throwing out vast showers of fire and cinders, with great darts of flame shooting up from 350 feet to 500 feet above the mouth of the crater. The whole country to the east and south was magnificently illuminated. At 3:40 A.M. two streams of lava could be seen running down the sides of the volcano, one to the south and east, the other to the westward. Dense masses of steam and smoke rose from the courses of the lava streams, as the shrubbery and foliage were burnt. The river Guacalate rose suddenly, and its waters were quite warm. Fuego continued to beich fire until daylight, by which time the whole northern horizon-looking from San Jose, was dark with the smoke from the The lava streams continued in view until 4:30 A.M. The first grand column of fire rose at least 500 feet in height, solid and smooth, and then the top, expanding, opened out like an umbrella, the sparks coruscating like those from a brilliant rocket. The pulsations of flame during the first two hours of the cruption were about 50 seconds apart, strong and regular. The cruption was less active until, at 7:30 P.M. on the 1st of July, a column of flame rose to a height, probably, of 150 feet or more. At the hour of writing Fuego smokes away steadily."

A Queer Locomotive.

The National Car Builder condenses from the Paterson (N. J.) Guardian, a description of a new locomotive now in process of construction at the Grant Locomotive Works, which, it is thought, will eclipse for speed anything yet built. It will look like an ordinary engine turned upside down. The machinery will be on top of the boiler instead of under it, as usual, and the boiler will hang very low on the wheels. There will be two pairs of driving wheels, but instead of having them follow each other, one pair will be on top of the other. The real driving wheels will be the upper pair, and they will turn in the opposite direction from that in which the engine is going. They will rest upon the rims of the other pair which will in turn rest on the the rims of the other pair, which will in turn rest on the The revolution of the upper pair, by friction, is ex pected to drive the lower pair, the tires of the latter serving as tracks for the upper ones. It is thought that a good deal greater speed can be got out of the machinery by this construction, and it is expected by the inventor that it will be the fastest locomotive ever made. Practical workmen, how-ever, think it won't go at all. It will look very funny as it is running through the country, with the upper pair of driving wheels, five feet in diameter, revolving up in the air in the wrong direction at a tremendous speed, and the eccentrics, rocking bars, link motion, and pistons on the top of the boller.

After Graduation.

A few years ago a young man of promise was graduated at Harvard University. He determined to become a cotton manufacturer. Instead of relying upon his general education, and waiting for an opening, as many of his classmates did, he began at once to prepare specially for the business he had chosen, by entering a machine shop as a workman—making full hours and acquainting himself with every part of the machinery of a cotton mill. From the machine shop he went into the cotton mill, and by hard work and close attention rapidly acquired a thorough knowledge of all the processes of cotton manufacture. While some of his classmates were waiting and looking for an opening in business, and others were with difficulty filling subordinate positions, and others were with difficulty filling subordinate positions, he was rapidly rising, step by step, until he is, to-day, in charge of one of the largest cotton mills in New England, with ample salary, and what is better, is discharging the duties of his position with great satisfaction to the company he serves.—Providence (R. I.) Journal.

Human Befrigeration.

Some experiments which seem to throw light on the physiological effects of bathing have been recently made by Dr. Paul Delmas, of Bordeaux. The action of cold and heat on the human system was studied by subjecting the whole body, except the head, of a healthy and robust subject to refrigeration with water at $+10^{\circ}$ C., in a suitable apparatus, the time of exposure varying from 15 seconds to 5 minutes. In some cases heat was applied previously. The pulse and temperature were noted all the time, and every five minutes in succeeding hours; the temperature by means of a thermometer placed in the mouth. The following effects were observed: During application of the cold, while the subject and is held beneath the animal's under lip. Ordinarily the shows every sign of very intense sensations (painful or other- spikes are prevented from pricking the horse by the curved durable, has been patented by Mr. Amedee Hourdeaux, of

wise), the temperature of the body scarcely varies at all, or varies at most one to two tenths of a degree, from that noted before; and previous heating does not affect this result. If, immedieating does not affect this result. ately after the application of cold, the subject remain perfectly still, after having been carefully dried and dressed, so as to avoid all active muscular movement, the temperature still varies little or not at all; but if he exert himself actively (in dressing, running, or walking), either immediately after the cold application or after a time of immobility, so as to bring on all the external phenomena of cold reaction, the temperature suddenly falls. The reduction persists several hours, and is more pronounced the stronger the sensation of heat in the subject. On the other hand, if chill continue or reappear owing to long immobility or suspension of exercise, the animal temperature does not fall, or immediately rises again. The amount of lowering of the temperature two or three hours after a cold application was, in eleven cases out of twelve, 0.1° to 0.6°. The maximum in a very vigorous subject never exceeded 1.3°. At the commencement of the cold application the pulse suddenly becomes very quick; after 10 to 15 seconds the velocity rapidly diminishes; and at the end of the experiment has returned to the previous figure or below it. If the subject, carefully dried and dressed, keep quiet, the retardation of the pulse stops or progresses slowly; but in the opposite case it is very pronounced, and persists the more the subject

pulse showed (in eleven cases out of twelve) two to twenty the springs and brings the horse's lip into contact with the pulsations fewer than before the experiment.

IMPROVED VALVE-GEAR FOR ENGINES

A novel device for reversing a steam engine is shown in the annexed engraving. The arrangement is such as to admit of reversing the valves when the engine is either at rest

The crank pin projecting from the crank disk, A, is elongated so as to be capable of engaging either of two lugs projecting from the face of a wheel, B, mounted on the inner The shaft of the wheel, B, carries a crank or eccentric which

of the craok pin with one of the lugs. When the engine is to be reversed the wheel, B, is turned so as to bring the opposite lug into position to be engaged by the crank pin. The valve is shifted by this operation, and when the engine is started its motion will be re versed.

To reverse the engine while in motion, an appliance consisting of a lever pivoted to the engine bed and carrying a shaft having friction wheels, C D, at opposite ends, is brought into use.

These wheels are capable of engaging with the wheels, A B, as shown in the detail view, and the wheel, C, is made smaller than the crank disk, A, so that'when it is brought into engagement with

the crank disk it will communicate motion to the wheel. B, through the friction wheel, D. By this means the wheel. B. will be turned ahead much more rapidly than as normal rate of speed, the valve will be reversed, and te lug on the opposite side of the wheel, B, will be engaged by the crank pin, and the engine will move in a reversed direction.

jection for engagement with the lugs on the wheel, B. d.iver or conductor.

These lugs may be secured to the wheel, B, by means of bolts working in slots, so as to enable the stops to be adjusted in order to regulate the lead of the valve.

This invention was lately patented by Mr. Peter Josserand, of Hockley, Texas.

HALTER TO PREVENT HORSES FROM CRIBBING.

The engraving shows an attachment to be applied to halters to prevent horses from cribbing and for curing them of this habit. The invention is shown in use in Fig. 1, and in detail in Fig. 2. A plate, A, carrying a row of spikes, B, is

MADDEN'S HALTER FOR PREVENTING HORSES FROM CRIBBING.

gives signs of energetic reaction and a general sensation of springs arranged on opposite sides of the row of spikes; but general alarm, and, after an interval, strike the box number Two or three hours after the cold application the the motion of the horse in the act of cribbing compre

> free movement of the head and mouth, but when the horse drops his lower jaw and seizes the manger, as in the habit of cribbing, the spikes will prick the under lip and the habit is soon broken up. This attachment is equally useful for vicious horses, as it prevents them from biting and tearing their blankets.

The invention has been thoroughly tested, and its merits are approved by horse trainers and owners. It was recently end of a shaft placed on the axial line of the main shaft.

The shaft of the wheel, B, carries a crank or eccentric which operates the slide valve, and it is driven by the engagement Park, N. J., who should be addressed for further information.

Louis, Mo., have patented a wrapper or jacket for bottles and

Mr. Johann W. R. Vogdt, of Potsdam, Prussia, Germany, has putented a curtain formed of a series of vertical strips or bands of cloth, or other suitable material, alternately attached to two rollers pivoted parallel to and adjoining each other in the top of the window casing, and provided with suitable cords or devices for rotating them both at the same time.

A blind adjuster and fastener, so constructed as to hold blinds in any position into which they may be adjusted, and prevent them from rattling, and which at the same time can be operated from the inside of the window and without raising the sash, has been patented by Mr. Charles L. Rainhart, of Catskill, N. Y.

A new attachment for basket handles, which is simple and

Lichtenfels, Bavaria, Germany. It consists of a staple passing through an eyelet at the end of the handle and through two slotted disks on the outer and the inner sides of the wicker work of the basket; the ends of the staple are then lapped down on the surface of the inner disk to prevent the staple from being drawn out by the handle.

Mr. Samuel P. Fraley, of Columbus, O., has patented a broom-brush that may be cheaply made by mechanical means, and is held together independently of the holder and handle without the use of stitches.

An improved terra-cotta kiln has been patented by Mr. Alfred Hall, of Perth Amboy, N. J. The object of this invention is to construct the doors of kilns for burning terra-cotta in such a way that the heat will be distributed equally through the door and the other parts of the kiln, so that all parts of the kiln will have a uniform temperature, and all the articles will be burned evenly.

Heretofore, where bells have been used for giving notice of fire, either by a general alarm or by striking the number of the signal box, much confusion has resulted from indistinct alarms or errors in counting. In some cases the fire alarm telegraph has been arranged to strike the number of the box, and bells not connected with the system are rung by hand, and it is of frequent occurrence that the box number is not heard at all except by the bell ringers. Mr. John H. Tilley, of Newport, R I., has invented a transmitter for fire alarm telegraphs that will first act to give a

and repeat the number, as required, thus calling attention, first, to the fact of the fire by an alarm which is likely to be heard, and then giving the locality.

Mr. David Untermeyer, of New York city, has patented an improvement in the class of necklace clasps which are provided with spring catches or fastenings for attaching the neckchain or necklace proper.

A rowing vehicle has been patented by Messrs. Charles E. Tripler and William H. Roff, of New York city. The object of this invention is to furnish wheeled vehicles that are operated by hand levers, and so moved that the operator, in propelling the vehicles, pulls the hand levers in substantially

analogous articles having spiral or diagonally arranged grooves or corrugations.

Mr. William T. Mc-Lean, of Sidney, Ohio, has patented an improvement in the class of earth scrapers or scoops having a thin metal body, formed preferably of rolled sheet steel, and a wooden back, which is secured to the body by means of clamps, etc. The improvement consists in the arrangement of the devices for securing the wooden back to the steel body of the scraper, and in providing the latter with a single longitudinal steel wearing piece or shoe, which is arranged centrally, and beveled on the sides and front end.

Amédée G. Sébillot, Paris, France.

patented an improved apparatus for the recovery of waste sulphuric acid. The object of the invention is to improve the product obtained from treating argentiferous ores, as well as to save the acid used in the process. An automatic fire extinguisher has been patented by Mr.

Edward Bocker, of New York city. The object of this invention is to furnish mecuanism to be connected with the faucets of water pipes, and so constructed that upon the rise the disk and crank pin, said crank is provided with a pro- of the car, so that they may be under the control of the of temperature in case of fire the faucets will be opened automatically and discharge water.

JOSSERAND'S VALVE-GEAR FOR ENGINES.

MISCELLANEOUS INVENTIONS.

Mr. Louis Prince, of Nashville, O.; has patented an improved car door operating mechanism for street or elevated railroads, arranged with transverse seats extending the entire width of the car, and provided with a series of doors upon the sides of the car which communicate separately with each The object of the invention is to provide means for When the crank shaft carries a regular crank instead of operating a series of such doors simultaneously from the end

THE INDIA-BUBBER AND GUTTA PERCHA INDUSTRIES.*

The lecture, of which the following is an extract, lately given by Mr. Thomas Bolas, F.C.S., before the Society of Arts, formed one of those admirable Cantor Lectures which are annually given to members. The importance of the India-rubber tree in connection with the many and useful purposes to which it is applied will be seen, upon a perusal of the lecture, which was opened by a description of the sources of India-rubber.

The earliest rumor of the existence of caoutchouc reached Europe nearly 500 years ago, the first visit of Columbus to Hayti having brought to light the fact that the natives of this island were in the habit of making playing balls of an elastic gum. Nothing more appears to have been heard of India-rubber until Torquemada, rather over 250 years ago, described the Mexican Indians as not only making balls of India-rubber, but also as fabricating helmets, shoes, waterproof fabrics, and other articles of elastic gum. We do not hear, however, of samples of India-rubber reaching Europe until long after this, and little more appears to have been learned regarding the substance until the celebrated French naturalist, La Condamine, made a communication to the Academy of Sciences at Paris concerning caoutchouc, he having had ample opportunities of studying the subject in Para. He tells us that the substance in question was used for making torches, these being only an inch and a half in diameter by two feet long, and yet burning for twelve hours. Again we hear of the use of India-rubber for playing balls, and it appears that the natives were in the habit of using enema or ejection bottles made of caoutchouc.

Soon after La Condamine's communication to the Academy of Sciences, samples of Indiarubber frequently reached Europe, and scientific men began to make investigations regarding this remarkable body. Between 1760 and 1770 we find Fresneau and Macquer studying the subject, and the last named investigator made tubes and other articles of caoutchouchy dissolving it in ether and coating moulds with the solution, so that a solid skin of caoutchouc should remain adherent to the mould on the evaporation of the solvent.

From this time until the end of the eighteenth century, the India-rubber industry may be considered to have been undergoing its period of gestation, and to have been born with the dawn of the present century. Among the first of the important patents regarding the utilization of caoutchouc is that granted in 1828 to Charles Macintosh, for dissolving the substance in coal oil, or coal naphtha, and the use of this solution as a waterproofing agent.

About the same time, elastic webbing was first made with threads cut from the raw rubber, and other minor applications of caoutchouc to the industrial arts were adopted from time to time, until the great discovery of vulcanization inaugurated a new epoch in this branch of industry, rendering it possible to so far alter caoutchouc as to make it capable of resisting, to a great extent, the action of heat on the one hand and cold on the other hand.

The milky sap of many plants contains caoutchouc, suspended in the form of minute transparent globules, these being frequently as small as one twenty-thousandth and one fifty-thousandth of an inch in diameter; but comparatively few plants contain sufficient caoutchouc to render them important sources of this body.

of this body.

The trees which yield the largest supply of the best quality of caoutchouc consist of various species of heven, which flourish in the northern districts of South America, especially in the province of Para, some portions of the valley of the Amazon being crowded to an extra-

* Land and Water.

Fig. 1.-HEVEA GUIANENSIS.

Fig. 2.—COLLECTING THE JUICE,

ordinary extent with heveas. The abundance of the India-rubber trees in Para may be judged of by the fact that this province alone exported 7,340 tons of caoutchouc in the year 1877, more than half of this being sent to Liverpool.

Among the heveas most productive of caoutchouc may be mentioned the Hevea brasiliensis, which flourishes in Para, and yields some of the finest caoutchouc, and often attains a height of sixty to seventy feet, with a diameter of nearly three feet; and the Hevea guianensis, a similarly magnificent tree, likewise abundantly productive of caoutchouc; and the Hevea spruceana, a smaller tree, which grows almost exclusively in the province of Para. The lecturer here projected on a screen a lantern slide, representing the foliage and flower of the Hevea guianensis, of which Fig. 1 is an illustration.

In collecting the juice, an illustration of the process being given by Fig. 2, a series of cuts are made through the bark of the tree; either shells or clay vessels are attached to receive the exuding milky sap, and when sufficient of this has been collected, the operation of drying it is performed as follows: A kind of wooden bat, thinly covered over with clay, is dipped into a pail filled with the juice, and the bat thus coated is held over a fire, fed with certain wild nuts, which in burning give off abundance of aromatic smoke. In Fig. 3, which represents this operation, it will be seen that a kind of short chimney is fixed over the fire to lead the smoke compactly upwards. As soon as the first layer of juice has become indurated, the bat is again dipped, and the drying operation is repeated, layer after layer being thus dried on the bat, until a thickness of nearly an inch is attained. A kuife cut is now made in the bottle or biscuit of caoutchouc thus obtained, so that it can be removed from the wooden bat and exposed to the air to become still furthur indurated. Para caoutchoue, if prepared in this manner, gives forth a fragrant aromatic odor.

The residues of juice left in the various vessels employed, the scrapings of the incisions, together with other materials which the ingenious native thinks he can shuffle off on the unsuspecting merchant as caoutchouc,

are made into balls, and sold as "negro head." The negrohead rubber is frequently made into crude representations of animals, which will pass about equally well for a horse, a pig, or a crocodile.

The milky juice of the Para rubber trees has approximately the following composition:

As a rubber producing tree, the Ficus elastica stands next in importance of the heveas. The Ficus elastica grows abundantly in India and the East Indian Islands, one district in Assam, thirty miles long by eight miles wide, being said to contain about 43,000 trees, many of them attaining a height of a hundred feet. This tree also grows freely in Madagascar, and it is well known to us as a greenhouse plant, a sketch of which may be seen on Fig. 4.

The juice of the Fieus elastica contains notably less caoutchouc than that of the American trees, the proportion very often falling as low as ten per cent of the juice. A vine-like plant, the Unceola elastica, which grows abundantly in Madagascar, Borneo, Singapore, Sumatra, Pensing, and other places, yields a considerable amount of caoutchouc of very good quality.

Africa yields a considerable quantity of caoutchoue, but generally soft and of inferior quality. It is believed to be yielded by various species of landolphia, ficus, and toxicophica.

Caoutchous is nearly colorless, and when in thin leaves tolerably transparent. It, like very many other substances, contains nothing but cashon and hydro-

gen, but its properties differ very widely from those of other hydrocarbons almost identical in composition. It has been found to contain, in one hundred parts, 12.5 of hydrogen and 87.5 of carbon.

Caoutchoue, as might be supposed, burns very readily, and leaves no residue. It is soft, and very imperfectly elastic, in the true sense of the term; that is to say, it does not return to its original dimensions after baving been considerably stretched.

As regards the stretching of India-rubber, there is a point at which it requires a greatly increased force to stretch it, and at this point it seems to become fibrous in texture, as you may perceive by examining this extended sample by the aid of a magnifying lens. India-rubber has valuable electrical properties, as you are no doubt aware, it being an admirable insulator, and having a remarkable tendency to become electrical by friction.

Freshly cut surfaces of India-rubber cohere very strongly when brought into contact, and this is well illustrated by the old way of making a tube of unvulcanized

Cold has a remarkable effect on caoutchouc, rendering it rigid and inelastic, and this circumstance considerably detracts from the value of unvulcanized India-rubber. A strip of India-rubber, soft and pliable, will, upon exposure for a few minutes to a temperature of 0° Cent., or the freezing point, become rigid and stiff, but its original pliability may be restored, either by warming or by applying sufficient tensile strain to it, to extend it to three or four times its length. In each case it is restored to its original condition. In the case of the stretching it is very likely that the effect is due to heat evolved during that operation.

The effects of heat on India-rubber present many points of interest. A band of caoutchouc attached one end to an index, stretched to the zero of a paper scale, will,

if a gentle heat be applied to it, contract, as regards length, but expands in a transverse direction, causing the index to move rapidly through a space of several degrees. This property, which stretched caoutchouc possesses, of contracting by heat, may be described by saying that within certain limits the tensile elasticity of caoutchouc is increased

by an elevation of temperature. Caoutchouc, however, if heated to 100° Cent., softens considerably, and almost entirely loses its elasticity, while a heat of 120° Cent. produces a most decided softening effect on caoutchouc of the best quality, but after exposure to this temperature it recovers its pristine state by exposure to cold for a moderate period. If, however, the action of heat has en pushed still further, say to 200° Cent., the caoutchouc becomes converted into a permanently viscous body, which has little or no tendency to harden again. This viscous substance possesses the same composition as unaltered caoutchouc, and is of value as a medium for making air-tight joints, which can be easily undone.

When caoutchouc is subjected to a temperature somewhat above 200° Cent., it becomes converted into a variety of volatile hydrocarbons, which present many points of interest, and you will find a tolerably full account of them in the manuals of chemistry. Indiarubber is subject to two kinds of deterioration and decay. In one instance it tends to become soft, and loses its elasticity, while in the other it becomes friable, yellowish, and resinous in its nature. The last mentioned kind of deterioration has been clearly and indubitably traced to an oxidation of the caoutchouc. This oxidation is tolerably rapid when the caoutchouc exists in a finely divided state and when it is exposed to damp at the same time; but the alternate damping and drying of the caoutchouc tends more towards its rapid oxidation than does a continual state of dampness. The resinous matter resulting from the oxidation of caoutchouc has been carefully studied by Spiller, who found that of felt, ori ton fibers and India-rubber, had become so far changed during six years as to contain no trace of caoutchoue; but in its place be found a resinous substance resembling shellac. This resinous body, of which a sample is before you, is easily soluble in alcohol, and also dissolves in benzole. Alkalies dissolve it readily, and acids precipitate it from the alkaline solution. It contains 87:8 per cent of

oxygen.

Fig. 3.-SMOKING THE GUM.

rubber takes place are not so well understood, but there is some reason to believe that this is due to incipient oxidation. Ozone oxidizes caoutchouc with extreme rapidity, as Warren pointed out in 1877.

It is extremely probable that the rapid deterioration of every kind of natural India-rubber contains two distinct

caoutchouc, which is known to take place under conditions which are not perfectly understood, is frequently due to the corrosive and oxidizing action of ozone.

Ozone, or some agent nearly resembling it, is often produced when oil of turpentine is exposed to the air, and this circumstance may perhaps explain the destructive influence which oil of turpentine occasionally exercises on India-rubber.

Exposure to sunlight often causes the destruction of India-rubber, either converting it into a soft and sticky substance, or into a bard body, less soluble in benzole than unaltered caoutchouc; and it is quite possible to obtain a photographic print by exposing a film of India-rubber under a negative, and then dissolving away those parts on which the light has not acted by means of benzole. It is generally a discreet thing to keep India-rubber where it will not be exposed to the prolonged action of a powerful light, although there are cases in which exposure to light is a useful aid to the process of vulcanization. India-rubber is, to a certain extent, porous and cellular in its texture, as may be seen by a microscopical examination of a thin section. Again, if a thin leaf of caoutchouc is boiled for a long time in water it absorbs a considerable proportion of this liquid. The amount may, in some cases, rise as high as 25 per In a similar manner alcohol is absorbed by India-rubber, but this fluid is absorbed more readily than is the case with water.

Now we pass on to a more important matter, namely, the action of such liquids as benzole or coal naphtha on caoutchouc. Here are two cubes of Para rubber, each being three-eighths of an inch across the face. One of these I will preserve as a pattern, and the other I will suspend in a bottle containing benzole. suspended in the benzole will immediately begin to swell, and will continue to do so

The conditions under which the softening of the India-| until it has attained a bulk about one hundred times as large as its original size. During the time that the cube is swelling in the benzole a certain proportion of the caoutchouc will become dissolved out, and incorporate itself with the bulk of the solvent. Now, as a matter of fact,

> modifications of caoutchouc, one of which tends to swell up in such a liquid as benzole, while the other dissolves and forms a true solution. The first mentioned of these bodies may be referred to as the fibrous constituent of caoutchouc, while the second may be spoken of as the viscous constituent. proportions in which these two bodies occur in raw rubber varies extremely; Para rubber, of good quality, containing only a small proportion of the viscous constituent, while African tongue, on the other hand, consists principally of the viscous modification of The viscous constituent of caoutchouc. caoutehouc is the agent principally concerned in the joining together of freshly cut edges of India-rubber. The treatment of the juice of the India-rubber trees is often of such a nature as to greatly deteriorate the caoutchouc obtained; a considerable proportion being thus changed from the fibrous to the viscous condition. This kind of injury to the caoutchouc can be obviated by coagulating the milky juice, and carefully drying the clot after it has been subjected to pres ure. For experimental purposes alcohol may be employed as a coagulating agent; while, on an industrious scale, alum has been tried with apparently an excellent result. The milk is strained to remove solid impurities, after which a small proportion of alum solution is added. The clot which separates is next drained or pressed, after which it is dried. Caoutchouc dissolves more or less perfectly, according to its condition, in various liquids, among which may be mentioned the various fixed and hydrocarbon oils, chloroform, ether, and carbon disulphide. Unless, however, the caoutchouc has been masticated or otherwise degenerated, it is doubtful whether a true solution is obtained. When a clear limpid solution is required, one of the best solvents is that proposed by Payen, namely, carbon disulphide, mixed with 5 per cent of absolute alcohol. If one part of masticated caoutchouc is dissolved in thirty parts of the above solvents a solution is obtained which can be filtered through paper, and may be employed in covering the most delicate moulds with successive layers of caoutchouc.

Caoutchouc may be utterly ruined by the use of impure solvents, and those experimenting with India-rubber solutions should in cases where it is desirable to regenerate the caoutchouc, by allowing the solvent to evaporate, take the utmost care not to employ any solvents which contain fatty or greasy matter.

Weak or diluted acids have little or no action on caoutchouc in the majority of cases, but strong sulphuric acid slowly acts on it, the action becoming rapid if heat be applied. Strong nitric acid acts on it with some energy, causing its entire destruction, and in a similar manner it is destroyed by the prolonged action of chlorine, bromine, or iodine; although these reagents, when their action is kept under control, have a vulcanizing or strengthening action.

A Peculiar Steamboat.

A propeller of novel construction has just been finished in San Francisco, California, to ply between that city and the Eel River Valley. The condition of the route required a staunch sea boat, which should also be of light-draught, to be able to cross the bar at the mouth of Eel River.

The vessel is 152 feet in length, 140 feet length of keel, 26 feet beam, 9 feet depth of hold, and will register 250 tons. When loaded with 300 tons of freight she will draw only 7 feet of water. She is flat-bottomed, but has a tapering bow and stern, and her lines are as beautiful and graceful as those of a yacht. The peculiarity of the boat consists in the arrangement of the two propellers. Instead of projecting from either quarter on either side of a single rudder there will be two rudders, and each propeller will be arranged with respect to its corresponding rudder, just the same as it would be if there were a single propeller. There are in reality three keels, the center one curving up at the stern, following the line of the vessel. Those on either side, however, are 13 or 15 feet apart, and run straight out beneath the stern, where there are two stern posts and two The spaces between the keels and the hull proper are filled in solidly with knees, strongly bolted in every direction. There is left between the two keels a wide space, which will give free access to water, so that each propeller will act as well as if it were the only one used to draw the boat. propellers are 6½ feet in diameter, of the Hirsch patent, and the pitch of the blades is set opposite, so that in going abead both will turn to the center. They will be driven by twin compound engines, set 9½ feet between centers, with a surface condenser between. The condenser will contain 756 tin-plated brass tubes, % inch in diameter, secured in end plates with a wooden ferrule, and affording 618 feet of cooling surface. The condenser will be operated by a Blake com pound air circulating pump, throwing 300 gallons per min-ute. The engines will have high and low pressure cylinders, the high pressure being 11 inches in diameter and low pressure 20 inches, with a 15-inch stroke. The steam will be supplied by a tubular boiler, with 3-inch return tubes. The engines will be so arranged that the engineer will face the bow, and will regulate his propellers by levers on either hand-pushing them forward when the bell signals "Go ahead," and bring-ing them back when he is signaled to back the vessel. The ngement of the propellers is such that one may be backed while the other moves ahead, and the boat can thus be turned in her own length. This is of especial importance, on ac of the narrow and crooked channel across the Eel River bar, where boats often ground because of their inability to turn quickly enough. The two keels under the stern will serve to protect the propellers if the boat grounds.

Water as a Prophylactic and a Remedy.

At the recent meeting of the American Neurological Society in this city, a paper was read by Dr. S. G. Webber, of Boston, upon this subject, from which we abstract the following:

Many people had a notion that it was injurious to drink at meals, but a moderate quantity of fluid taken at meal time was rather beneficial than otherwise. A large class of patients were affected with symptoms of an indefinite character—a vague unrest, showing itself by discomfort or even pain, sometimes in one place, sometimes in another. They were usually subject to constipation, often had an unhealthy hue of the skin. They were frequently classed as hypochondriacal or hysterical. There was no well defined These patients usually drank too little water. The waste of the tissue changes in the system must pass into the blood, and could only leave the system in a state of solution. During comparatively good health, the amount of blood was maintained at nearly the same figure, and only so much water would be parted with through the skin, lungs, and kidneys as could be restored from other sources. If too little water was ingested, the perspiration would be slight, the elimination of urine would be diminished, and the excretion of waste material would be lessened. The blood would be continually saturated, or nearly so, with the results of disassimilation. The removal of the waste of tissue changes was not accomplished with sufficient regularity, and the tissues became clogged with used up material and nutrition was interfered with. The balance each day against health was very slight; but after a time there wa cumulation that unpleasant symptoms were developed. If the person continued to eat heartily, either the surplus food passed off by the intestines, or was deposited in the shape of fat, the nitrogenized portions assisting to load the urine with urea and the urates. Let such a person unt, and the blood, having a sufficient sup- pressure. - Photographic News.

ply of water, more urine would be secreted, the loss made good to the blood by absorption, and a larger amount of waste products would be taken up to be eliminated; more urea or phosphoric and sulphuric acids passed off by the urine, which was increased in amount, and there was more disintegration of the tissues. This last was made up by new material, so nutrition was increased. The doctor found that neurasthenic matients did not drink enough.

found that neurasthenic patients did not drink enough.

Dr. Beard remarked that he had found thirst a prominent symptom of neurasthenic patients. He had been using Summit water with good results. He used the bromides alternately with tonics and a free supply of water. The plan was very satisfactory.

Dr. Webber said that patients who drank no more than a pint or twenty ounces of water per day, had told him that they were not thirsty, and were surprised when he told them to drink more water. These directions being compiled with, the patients, in the course of the week, developed thirst, and drank as many as three pints a day.

Analyses of Baricy, Rice, and Maize.

Enemies of the Tea Plant.

Speaking of blight, we think that if more care was taken to watch its first appearance, many of the remedies prescribed might be possibly effectually applied. But when blight has been allowed to spread over a large area, it becomes almost impossible to stop it. Bushes on which blight appears should be promptly treated, wherever possible, and different known remedies tried. It is seldom that an area is attacked all at once, and there is no doubt that with spider and at me other blights, they are carried about by the coolles from bush to bush. It is generally supposed that heavy rain washes away the red spider. To a certain extent, no doubt, it does, but the creature has a trick of getting underneath the leaf when he finds the moisture too strong for him, and when the warm sun comes out again he recommences his peregrinations and destructive action over the surface of the leaves. The activity of the insect is something surprising, and an investigation, under the microscope, of the leaves attacked will show them transparently red, and covered with hundreds of eggs, with little spiders emanating therefrom and cutting about with amazing vigor. The unhatched eggs (that is those not yet matured) are unfortunately not destroyed or washed off the bush by the rains, in consequence of being practically gummed to the leaf, and thus a second syringing or treatment should follow very quickly. If heavy rain falls at the right time, it may save the trouble of syringing.

Besides the red spider blight, the Darjeeling district is suffering from green fly blight. This pest eats the outside of the stem of the flush, causing the leaf to curl up and wither by reason of the sap being prevented from rising. There is also the red bug, which cuts through the upper shoot of the flush, and makes it droop off. Then the mosquito blight, which, puncturing the leaf, and preventing the distribution of sap, hardens it.—Indian Tea Gazette.

Distortion of Lenses by Pressure or Strain. Many photographers have from time to time remarked

that it is occasionally impossible to focus an object sharply and clearly, even with a lens known to yield a satisfactory result in ordinary cases. Setting aside such obvious cause as light shining into the lens, or the presence of moisture on one of the glasses, there can be little doubt that the most frequent source of the difficulty in question is a bending or distortion of the objective by some mechanical force acting on it. In the case of lenses burnished into their mounts, a contraction of the ring by cold may distort the lens uniformly, if its fit in the mount is accurate, merely altering the focus and disturbing the corrections of the instru If, however, the cell in which the lens may be mounted is not turned with extreme accuracy, or if the outside of the lens itself is not truly round, so irregular a distortion may arise as to altogether destroy the defining power of the combination to which the lens belongs. There is no question that the practice of burnishing lenses into their mounts has its disadvantages, for when this plan is adopted the operator has no easy remedy against a "frost-bound" lens, excepting to keep the instrument warm during the time he is using it. If, on the other hand, the glasses are not comented in their cells, they are liable not only to be misplaced by careless persons, but also to be distorted by bring screwed down in their places by an undue degree of force. Lenses should generally be left just the least bit loose in their mounts not quite enough to cause any possibility of shaking, but the right degree of looseness can generally be estimated by

ENGINEERING INVENTIONS.

An improvement in endless cable railways has been patented by Mr. Samuel M. Pettengill, of Brooklyn, N. Y. If relates to railways provided with a moving endless cable, rope, or chain, for propulsion of the cars. The object of this invention is to furnish the cars with means for seizing and denter heading to the rope of the representation.

firmly holding to the rope or cable without shock.

Mr. James B. Jenkins, of Warren, Ill., has patented a grapple for lowering pipes into wells that may be detached from the pipe automatically by sliding it down on the pipe until it comes in contact with a coupling.

until it comes in contact with a coupling.

An improvement in that class of railways in which no wooden ties are used, and the pot sleepers or chairs are flared to rest directly upon the ground, and are cast in one and the same piece with a jaw which is perforated with holes for the fish bolts, between which jaw and the fish plate the rails are bolted, has been patented by Mr. William Rainbow, of Chancery Lane, England. The improvement consists, mainly, in the means for connecting the chairs so as to preserve the gauge of the road.

A clock device to be used on railroads to be operated by passing trains, whereby the time clapsing between the passing of one train and its next succeeding one will be correctly indicated to the engineer of the succeeding train, has been patented by Mr. Alma P. Burroaghs, of Seneca Falls, N. Y.

Mr. Augustus B. Wood, of Fountain Hill, Ark., has patented a cheap and economical oscillating engine furnished with a valve so arranged and controlled that friction and pressure upon the valve seat are reduced simply to that which is necessary for preserving a steam tight joint between the two.

An improved low-water alarm for boilers has been patented by Mr. Nathan L. Adams, of Fort Collins, Col. The object of this invention is to furnish steam boilers with an improved device that will indicate automatically and give an alarm when the water in the boiler falls below the safety point.

Mr. Anton Pohl, of Baltimore, Md., has patented an improved spark arrester, in which the joint action of gravity, deflection, and centrifugal force is employed to separate the sparks, cinders, and solid matter from the smeke as it escapes through the stack of a locomotive, whereby the work may be effectually accomplished within the limited space of the stack without materially intercepting the draught. The improvement consists in arranging an annular chamber around a cylindrical stack, and providing the stack with a spiral deflector plate, which will give a rotary motion to the smoke and cause the solid matter to be thrown off against the side walls of the stack, where it is intercepted by projecting plates and conducted through openings into an adjoining annular chamber and deposited at the bottom.

An improved car coupling has been patented by Mr. Edward S. Plimpton, of Denison, Ia. This invention is an improvement in the class of car couplings in which the coupling pin is provided with an arm that projects from the head thereof and rests in a socket in the front tep portion of the draw head, so as to constitute a fulcrum on which the pin may swing when pushed back by the link in the operation of coupling.

A Magic Lantern and Six Slides for Six Cents.

A small tin lantern, about three inches high, with lamp, slides, and two lenses, is actually being now sold in London at the above mentioned price; while a larger one of a similar character costs the somewhat more extravagant sum of fifteen cents. The small lantern is of German make, and when one considers that the manufacturer cannot get more than four cents for the article, it is a matter of wonder how it can be produced for the price. Very little can be said as regards the artistic merits of the slides, but like the old Dutch tiles, they at least possess the merit of being hand-painted—if, indeed, this be a merit. The lenses, which, as gards optical work, are superior to many spectacle glass old in London, give, as an advertisement would put it, " brilliant illuminated disk six inches in diameter," also sold in London at the present time, a toy camera-obscura about the same size as the magic lantern in question. Who knows but what the present pushing age may produce a small tin photographic camera, double alide, two dry plates, and lens for about 25 cents? It could certainly be done if the work were executed on the same scale of cheapness as in the case of the magic lantern. It is, perhaps, not generally known that a very passable photograph can be taken with a common penny magnifying glass, if it be stopped down and a proper adjustment made for the difference existing between the chemical focus and actinic focus.—Photo grophic News.

Brilliant Tints of Californian Flowers.

the disadvantages, for when this plan is adopted the operator has no easy remedy against a "frost-bound" lens, excepting to keep the instrument warm during the time be is using it. If, on the other hand, the glasses are not comented in their cells, they are liable not only to be misplaced by careless persons, but also to be distorted by being acrewed down in their places by an undue degree of force. Lenses should generally be left just the least bit loose in their mounts—not quite enough to cause any possibility of shaking, but the right degree of looseness can generally be estimated by making an attempt to turn the lens in its setting. Few persons realize the ease with which glass bends and yields to pressure.—Photographic News.

Under the title of "A Botanist in Southern California," Mr. J. F. James contributes to the American Naturalist some interesting sketches of the vegetation of the country in the vicinity of Los Angeles. Rain falls there only from November to March, and the rest of the year is bot and dry. By the middle of June or July vegetation is parched up, and the country has a very depressing aspect; but the spring is glorious. Then the plains surrounding the city, the hills, and the valleys are one mass of gorgeous, brilliant flowers.

They are there by thousands upon thousands, and of almost endless variety. Most conspicuous of all, both for its abundance and its color, is the Californian poppy, Eschacholtsia californica. It covers acres of ground, and the bright

golden-yellow or orange of its flowers is visible for miles. When the sun is shining full upon it, it is too dazzling for the eye. In places where the ground was plowed paths of it had been left, and they seemed like tongues of fire running over the ground. Among other showy plants are Sidalcea maleaflora, with large purple flowers; Platystemon californious, called cream-cups; Dedecathon meadia; Baria gracilis, a composite with bright yellow flowers, covering acres of ground; Paonia brownii, in tufts, with large purple or readish flowers; various species of Gillia, Pents Lobelia, Phacelia, Nemophila, together with Clarkia, Salvia, Castilleia, Convolvulus, and Colochortus, making up such a wealth of color as is rarely seen elsewhere.

THE CONCH FISHERIES OF THE BAHAMAS.

BY W. H. WEE

Conch fishing in the Bahama Islands is quite an extensive industry. There are about 500 vessels engaged in this and the sponge and turtle fisheries. Most of these from time to time engage in conch fishing according to the demand for

The vessels employed are either sloops or small schooners, and carry from three to ten men, most of them of the "colored persuasion." These negroes are expert divers and swimmers, being accustomed to the water from childhood. They enjoy the distinction of being perfectly fearless, even in the presence of that dreaded enemy of divers, the shark, who is found in abundance in these waters. It is a current saying in Nassau, when a stranger asks if the negroes are not afraid of sharks, that "a shark will not attack a nigger." The men usually work on shares, and their reward being thus dependent upon their own exertion, each one spurs the others at their work; they all labor with more energy than is usually characteristic of their race in this climate. The couch, which is like an enormous snail, is found in the shallow waters of this vicinity, the sea bottom of the numerous shoals being a favorite place for them. The larger crews work in parties of two, three, or four, in separate boats and independent of each other.

In order to locate the position of the fish they use what is alled a "water glass." This is a rectangular water-tight called a "water glass." box about thirty inches long, with one end a foot square, and closed by a pane of ordinary glass. The other end is slightly larger and is open. In using the "glass" the closed end is immersed in the water a few inches below the surface, when the sea bottom is distinctly visible through the glass, the water being clear as crystal.

Having discovered the position of the conch the diver leaps in and obtains it, and in a few moments is back in the boat looking for more. Some of the fishermen use a double pronged hook attached to a long staff, such as is used in aponging, and with this secure the conch instead of by div-

When a boat load is secured the conchs are taken ashore to some convenient beach and left to die. When dead the shells are beaten against the soft sand, which loosens the flesh so it may be easily removed.

The meat of the pink conch is carefully examined for pearls, but the other varieties have no pearls.

The shells of the pink couch are scraped to remove the seaweed, serpulæ, or other incrustation, but the others are naturally pretty clean and are sold in the rough state.

The length of the cruise varies, of course, but the usual time is three or four weeks. On the return to Nassan the shells are sold to the conch dealers or merchants, who sort and pack them for shipment. The finer specimens are packed in cases with sponge clippings, but the ordinary kinds are packed in bulk or shipped loos

Most of the exports are to England and the United States,

though France takes a good many from English consignees. The four varieties of conch which form the basis for this industry are the common or pink conch, the milk conch, and the king and queen conchs. The first, the Strombus gigas, is the most common, and is the well-known conch used for ornamental purposes. It is also the same formerly used for the dinner horn by many old farmers; indeed, it still does good service in that line in the far West.

The flesh of the snimal is edible, making, when cooked and properly dressed, a very fair salad, as the writer can testify from experience.

The shell is used for turning into sleeve buttons and brooches, much in vogue in Naples, Italy, but for some unknown reason they do not take well in the United States. Exquisite pink cameos are cut from this shell, and are often mistaken for coral by novices.

Many tons of this shell are also used in the porcelain manufactories of France and Germany.

The milk couch is also one of the strombs and is much smaller than the pink conch. The name is derived from the milk-white color of its interior. The shell is much less fragile than the other species, and it is used in the United States for ornamental purposes

The queen (Cassis madagascariensis) is a much more valuand the king conch is very valuable in cameo cutting, and are much used for this purpose in England and France.

The king couch is of the same species as the queen, but it differs somewhat from it in having a triangular face of a brownish yellow, and the interior of the shell and around the toeth is of a purple black.

Several very handsome specimens with cameos cut in the

shell may be seen in the Bethnal Museum, London, and at the American Museum of Natural History in New York.

The pearls taken from under the apron of the pink conch are either pink, yellow, or black. The pink are, however, the only valuable kind. These are of that exquisite shade of pink which gives the name to the conch from which they are taken. Many of the pearls are beautifully water lined, and this, together with their size and color, determines their worth. The lucky fisherman who has any of these pearls for sale finds a ready market for them in Nassau, where the buyers offer very good prices for the pearls, £20, or \$100, is not a very unusual price, though the majority of the pearls bring a very much lower figure, of course.

The buyers export them to England, where the demand is good. They may be seen in London set in all sorts of ways, the favorite being in the form of rings, which can be bought from £2 up.

The value of the pearls annually exported from Nas

was recently estimated at £10,000, or \$50,000. The value of the different conch shells in New York is, for the pink conch, \$4 per one hundred shells; milk conch, \$6.50; king conch, \$25; queen conch, \$20.

NATURAL HISTORY NOTES.

Old Seeds versus New .- There is a widespread impression that old seeds of many plants are preferable to new, especially in the production of double flowers. Desirous of putting his view to the test, an experimenter, whose results are recorded in a recent rumber of the Revue Horticole, undertook a series of experiments with the seeds of the camellia-flowered balsams of varying age. The conclusion arrived at-diametrically opposite to the generally received opinion—is that it is the youngest seeds which give the largest proportion of double flowers.

The Potato Grafted on the Bitter Sweet,-An experiment has been performed by M. Lambotte, the record of which, together with an illustrative woodcut, may be found in a recent number of the Revue Horticole. M. Lambotte tells us that in the spring of the year, while picking out some potatoes for culinary purposes, he remarked one sprouting and more fit for planting than for cooking. He had at the time, close at hand, a plant of the bitter sweet (Solanum dulcamara), the stem of which he cut to a sloping point, which he introduced into a hole in the potato as deftly as possible. Some days afterward the potato had regained its hardness and speedily sprouted from the eyes, the principal stem measuring more than sixty centimeters. The tuber became green, excessively hard, and developed little shoots bearing smaller tubers and rootlets. In point of fact there was a tuber growing in the same manner as it would in the ground, and only differing from an ordinary tuber in its hard consistence. Things went on in this manner till the end of September, when suddenly the leaves withered and the oots became pendent, and the tuber gradually became soft and decomposed after its ten months' sojourn on the stem of the bitter sweet, the latter continuing its growth in the ordinary manner, unaffected by the fate of its quondam associate.

The Eggs of the Great Auk.—The numerous bones of the great auk found on the shores of Greenland, Newfoundland, Iceland, and Norway attest the former great abundance of this bird, but within the last century it has gradually become more and more scarce, and is now believed to be extinct, none having been seen or heard of alive since 1844, when two were taken near Iceland. There are but three specimens in the United States-one in the Academy of Natural Sciences at Philadelphia, one in the Smithsonian Institution, and one in the Cabinet of Vassar College. The last is the most perfect specimen, and posse ses the greatest bistorical value, as it is the one from which Audubon made his draw ing and description. The eggs of this extinct bird are also extremely rare, and it is, therefore, interesting to learn that two specimens have been recently discovered in an old private collection in Edinburgh and sold at auction. The prices realized on these two rarities were \$560 and \$500 respectively. The purchaser was Lord Lilford.

A Case of Apparent Insectivorism. - Professor Baillon, at a recent meeting of the Linnean Society of Paris, read the following notes on the apparent insectivorism of a plant often seen in cultivation, Peperomia avifolia, of which the variety Argyreia is cultivated in so many greenhouses, has the leaves more or less deeply peltate. I have seen stalks on which the peltation on certain leaves was so exaggerated as to show on cross section a depth of nearly four centimeters. When the concave stalks take a suitable direction, water (principally that from sprinkling) would accumulate it. Many small insects would fall into this water and be

and rest in these receptacles, so well prepared to preserve drowned. Last year, when the season was warm and when the windows of the house were often open, the number of insects was very considerable, and these, soaking in the water, gradually fell into decay, and it was remarkable that there was during this not the least sign of any putrescent odor. Those who believe in the theory of insectable shell than the preceding varieties. Its flat face is egg eating plants may perhaps in this be led to find an argument shaped and of a handsome salmon red color, being of a favorable to such doctrines. They will add that the variety beautiful brownish black near the teeth. The shell of this of colors so strikingly seen in these leaves constitutes the agent of attraction for the insects to come and be drowned. These reflections, each of a different sort, here present themselves: 1. Is it not remarkable that the exaggerated peltaselves: 1. Is it not remarkable that the exaggerated peltation of these leaves is in this case accompanied by an apparent insectivorism, and that the leaves of the plants known up to this time by botanists as carnivorous owe their saclike, born-like forms only to an excessive peltation of their

limb, as we demonstrated in the evolution of the leaves of Sarracenia (Comp. Rend. lxxi. 630)? 2. How can it be considered as a proof of insectivorism, that plants such as the Utricularia grow better in a fluid containing albuminoid compounds, when other plants grow equally favorably in the same kind of fluid, and which latter are never for a moment thought of as carnivorous? 3. How do the chief priests of our science reconcile the two ideas, that the surface of the leaves of plants is unable to absorb pure water in contact with them, and that the same surface daily absorbs water charged with albuminoid substances and the

Albino Arethusa, -A white flowered variety of this rare and beautiful North American orchid has recently been discovered in Rhode Island by Professor W. W. Bailey. It has the yellow markings of the labellum, as in the ordinary red flowered form. In his "Wild Flowers of America," Professor Goodale states that the plant grows in bogs, with its corm embedded in peat moss, sometimes two or three inches below the surface.

CURIOUS FACTS ABOUT THE ALBATROSS.

The tracts of lower, nearly flat land of Marion Island, skirting the sea, and the lower hills and slopes along the shore, presented a curious spectacle, as viewed from the ship as it steamed in towards a likely-looking sheltered spot for landing. The whole place was everywhere dotted over with albatrosses, the large white albatross or goney (D. exulans). The birds were scattered irregularly all over the green in pairs, looking in the distance not unlike geese on a

The albatrosses were all around, raised from the ground Their nests are in the style of those of the mollymanks, but much larger, a foot and a half at least in diameter at the

They are made up of tufts of grass and moss, with plenty of adhering earth beaten and packed together, and are not so straight in the sides as those of the mollymanks, but more conical, with broad bases. The female albatross is sprinkled with gray on the back, and is thus darker than the male, which is of a splendid snow white, with the least possible gray speckling, and which was now, of course, seen in his full glory and best breeding plumage; the tails and wings of both birds are of course dark.

The albatrosses one meets with at sea are most frequently birds in young plumage or bad condition, and have a rather dirty, draggled look. The brooding birds are very striking objects, sitting raised up on the nest, commonly with the male bird beside it. They sit fast on the nest when approached, but snap their bills savagely together, making thus a loudish noise. They will bite hold of a stick when it is pushed up against their bills. They need a good deal of bullying with the stick before they stand up in the nest and let one see whether they have got an egg there or no. Then the egg is seen to appear slowly out of the pouch in which it is held during incubation. It is nearly five inches long, or about as big as a swan's, and is white, with specks of red at the large end. Only one egg is laid. In most of the nests there were fresh eggs; in some, however, nearly full-grown young birds.

At Campbell Island, of the Campbell and Auckland group, the young of Diomedea exulans were found just breaking the shell in February, by an exploring party.*

Charles Goodridge, who was one of a sealing party on the Prince Edward Islands in 1820, and spent two years on the Croyets, says that the albatrosses there lay at about Christmas, and that the period of incubation is about three months (?). The young, he says, were wing-feathered, and good to eat about May, and did not fly off till December.

The young albatrosses are dark-gray in plumage. They map their bills, like the old ones, to try and frighten away enemies. The old birds never attempt to fly, though persistently ill-treated or driven heavily waddling over the

Very many were killed by the sailors that their wing bones might be taken out for pipe stems, and their feet skinned to make tobacco pouches. The old males tried to run away when frightened, but never even raised their wings.

It is amusing to watch the process of courtship. The male, standing by the female on the nest, raises his wings, spreads his tail and elevates it, throws up his head with the bill in the air, or stretches it straight out forwards as far as he can, and then utters a curious cry, like the mollymanks, but in a much lower key, as would be expected from his larger larynx. While uttering the cry the bird sways his neck up and down. The female responds with a similar note, and they bring the tips of their bills lovingly together. This sort of thing goes on for half an hour or so at a time. No doubt the birds consider that they are singing. Occasionally an albatross flies round and alights upon the grass, but I saw none take wing .- H. N. Moseley .- Challenger Notes.

A Wisconsin cow died not long ago, after a lingering illness, attended by a persistent cough. After her death a veterinary surgeon opened the windpipe to discover the cause of the irritation, and found in the upper part of the lung a live striped frog of ordinary size. The surrounding portion of the lung was much discolored.

Any numbers of the SCIENTIFIC AME fice. Price 10 cents each.

- (1) G. A. A. asks: Which is the best pipe o use for heating a room with steam: two rows of one ch pipe or one row of two inch pipe? A. If the radiating surface in the two cases is the same theoretically there should be no difference, but practically we slieve the smaller pipes have proved more efficient.
- (2) O. V. D. asks: 1. How many pounds ight a three-eighths inch bar magnet h ought a three-sighths inch bar magnethold up, like that described in the SUPPLEMENT, No. 142, in the article "How to Make a Working Telephone," Fig. 4, so that I could tell if it was charged powerful enough? A. About three-fourths its own weight. 2. What would be the numbers of the lenses required to construct a spy giase like that on page 68, SCHENTERO ANKRICAN, No. 5, Vol. 48? A. Only two lenses are required. The object giass should be achromatic, the eye lens is double
- (3) Dr. A. M. C. says: I want to make a sidewalk 10 feet long, 21/2 feet wide. What can I use in place of stone or wood, something that is durable and hard? A. You might use ordinary cement, three inches thick, which any mason can put down for you. See Supplements, 33, 36, and 33.
- (4) W. H. D. asks: 1. Will a magnet that will lift a one pound weight make a small machine that will make a small current to show how it works? A. Yes. 2. Will sheet glass covered with tin foil on both eides make a Leyden jar, and by combining a large number together, having the negative sides connected and all the positive sides connected, make a powerful batall the positive sides connected, make a powerful bat-tery? A. Yes, but the jars are better. S. Would not sheet lead answer as a substitute for tin full? A. Tin full is best.

- method of, preventing woodwork in mills saturated with oils from taking fire in the event of a blaze touch-ing the woodwork. A. Woodwork strongly impregnated with tungstate of soda or silicate of soda (by treatment
- (6) G. E. writes: 1. I have bought some (6) G. E. Witten: 1. I have tought some woolen underclothing which are so much filled with sulphur that they are very anpleasant to wear. Is the sulphur injurious to health? A. Yes, if present in considerable quantity. 2. What will remove the sulphur? A. Salphur is soluble in bisulphide of carbon. If the bisulphide used is pure the small quantity adhering to the cloth after wringing will quickly and completely evaporate on exposure to the air.
- (7) R. P. asks if there is any indelible pre ation for stenciling on unplaned lumber, as is, etc., in black or other colors? A. Use a centhe solution of asphaltam, tempered with
- (8) J. G. asks what are the plates on which photographic pictures commonly called tintypes are taken coated with? A. The places are flowed evenly with japan varnish, and the coating hardened in a japan' new years. The varnish may be procured at almost any paint store.

(9) P. T. asks how to take stains made by Payson's indelible ink out of lines? A. Moisten with a little iodine, then with ammonia water, and rince in

(10) E. H. writes: 1. Referring to your description of Blake's transmitter, on p. 274, vol. 41, Scientific American, how is the brass button filled with carbon? A. The brass is spun over the carbon. 2. Is it the carbon that weighs three pennyweights, or brass and carbon together? A. Both.

(11) W. S. H. asks: Can you give a simple (11) W. S. H. asks: Can you give a simple test for oxygen water; that is, water supposed to contain an extra amount of oxygen—all it will take up? This water is called by some oxygenaqua. A. Filia quarbottle, provided with a perforated cork (tightly fitting to admit a glass tube, with the water; heat nearly to boiling, and collect the gases given off in a small test tube, by displacement, over the pneumatic trough. Examine the gas with an ignited taper or splint of wood Momentary increase in the intensity of combustion of access an unusual amount of oxygen in the water. Compared to the water. sual amount of oxygen in the water. Com ults with ordinary well or cistern water

(12) E. T. S., St. Clair, Mich., says: In e of August 14, G. G., in the article, "Evolution "speaks of the "golden cut." Will you please what is meant? A. To divide by the "golden of Ideas," speaks of liinstrate what is m instrate what is mean? A. To divine by the goods-ing by "extreme and mean ratio," and this means, as G. 3. correctly remarks, the dividing (of a line, for example) in such a manner that the whole has the same relation in such a manner that the whole has the same relation to the larger part as the larger part to the smaller, and vice verse. Let A B be the given line which is to be divided by the "golden cut." At B draw to A B the perpendicular B E, equal to one-half of A B. With E as center and A B as radius describe a circumference. Draw the straight line A E G, cutting the circumference.

in F and G. On A B lay off A C = A F, and on the principal of B A lay off A D = A G. Then the line A is divided interally at C (and externally at D) by the golden cut," or in extreme and mean ratio. For sin A B is a tangent and A G a secant, A B is, "according to a well known thesis of geometry, a mean proportional between A G and A F.

A G : A B : : A B : A F A G - A B : A B : : A B - A F : A F F G = A B also A C = A F AC: AB:: BC: AC AB: AC:: AC: BC

The first proportion by comp sition gives:

A G + A B : A G :: A B + A F : A B Since A G = A D and A B = F G we have B D : A D :: A D : A B.

- (18) F. P. S. asks: 1. Can paper be made (13) F. P. S. asks: 1. Can paper be made to have the same strength and elasticity as leather? Can it be moulded into a form \$\pi \mathbb{R} \ma
- (14) C. W. H. writes: I wish to learn how (14) C. W. H. writes: I wish to learn how o mix shellac in liquid form, to be used in shellacking a cedar boat; that is, how much alcohol to a certain mount of shellac should be used, and how it should be pplied so as to obtain a thin hard coating that will wear real. A. Place two pounds of orange shellac in a jug or iomijohn, and pour over it one gallom of 95 per cent alcohol; allow it to stand for a day or so, shaking it occasionally, and stirring if it becomes solid at the bottom. When the shellac is entirely dissolved strain the armish through a piece of flannel. Apply with a flat, of through a piece of flannel. Apply with a flat,
- (15) F. E. T. asks: What is nickel silver (10) F. E. T. ASKS: What is micked silver jeweiry? I wish to get some of the metal, but flad none advertised. A. German silver (a nickel silver) is composed of: 1. (for easting)—copper 6, zinc 2, nickel 3½. The specimen metal sent is lead superficially rolled with tin.

(5) J. S. M. inquires as to the best of swamp muck. Please inform me how nilrogen is manufactured from swamp muck? A. Muck contains a large per cent of certain nilrogenous compounds, the gibe woodwork. A. Woodwork strongly impregnated thit tungstate of sods or silicate of sods (by treatment atrong aqueous solution of these saits) becomes unflammable.

(6) G. E. writes: 1. I have bought some

(17) M. F. P. writes: I would like to get the details of lacquering brass goods, such as lamps, springs, etc., to keep them bright and prevent them from tarnishing. See pp. 306 (15), vol. 42; 44 (16), vol. 88; 44 (50), and 188 (52), vol. 87; 842, vol. 34; 189 (41), and 336, vol. 32, SCHENTIPIC AREBICAN, and p. 630, No. 88, SCHENTIPIC AREBICAN SUPPLEMENT.

(18) J. J. M. asks (1) if a dynamu electric nachine will run of itself, or if a battery is applied to b. A. A dynamo-electric machine will guarante an lectric current without the aid of a battery. 2. What number of wire would I need to make bobbins 2 inches ong, I inch in diameter? A. It depends on the style of the machine. See article on small electric machine in SUPPLEMENT 161.

(19) C. E. W. writes: I have both copper and brass moulds for small sricles, but meet with failure in the metals not running sharp in the small lines. Have tried smoking, but does not work. What can I do to remedy it? I use the most fasible alloys. A. Heat the moulds well before pouring, and coat them mouthly with black lead. hly with black lead.

(20) G. M. B. asks: 1. How is nitroglycerine made. A. Nitroglycerine is prepared by bringing glycerine drop by drop into a cooled mixture of very strong nitric and sulphuric acids. The nitroglycerine collects at the bottom of the vessel and is subsequently freed from the acids by carefully washing in a copious supply of water. 3. Is the explosion canned by the rapid transformation of a solid into a gas? A. Yee, in the case of nitroglycerine from the liquid to the state. S. Would not iron, wood, or any substate. plosion if instantaneously changed into a gaseous rm? A. Yos. 4. Are the nitrates the only explosive betances known? A. No, ganpowder prepared with lorate of potash explodes more violently than that in sich niter is used.

(21) H. B. C. writes: Will you please in (21) H. B. C. writes: Will you please inform me the best way to cut caruellan and moss agates? A. Some specimens may be readily cut by means of a thin rotating iron disk charged with emery and water. Extremely hard specimens require diamond dust. It should be mixed with a little clive oil and applied sparingly to the edge of the disk. To cut plane surfaces and facets on these stones use a flat lead lap wheel charged with emery and water. Polish with rotten stone and water applied to a pewter lap.

(22) E. F. L. asks how to cut and finish arnelians and agates. I have a United States dental athe. A. See reply to H. B. C. above.

(28) C. & W. write: 1. We are putting in (23) C. & W. write: 1. We are putting in a sixty horse power locomotive pattern bollor. Shell 60 inches in diameter. We use the exhaust steam in a dry house. As we cannot use exhaust steam for heating water, we have extended the space behind the tubes four feet, and propose putting in a ceil of 400 feet of 114 inch pipe through which water will be forced. The heat after passing through the tubes will st. the this ceil. Is the plan a good one? A. Your plan would heat a limited quantity of water. B. Is it advisable to use steam jet instead of scraper, for cleaning tubes? A. The steam jet is used very successfully. 3. Should we run exhaust steam through a boiler, say thirty minutes, then close all openings except a pipe running down to water afteen feet below; would not the steam condense and partially fill the boiler? If so, how full? 8. Yes, probably fill the boiler entirely.

(24) W. E. F. writes: In your Scientific

(24) W. E. F. writes: In your SCIENTIFIC (24) W. E. F. writes: In your SCIENTIFIC AMEMICAN and the SUPPLEMENT you speak of preserving iron in water and ships' bottoms by the application of crecoste. Is it oil of crecoste as sold by druggists, and can it be applied with a brush on the outside? I am putting in a flume 60 feet long by MEXIS; can I so coat the timbers? Also, I have a fine yacht: can I, when I hand her out for the season, and got her well dried under cover, paint her invide and out with oil of crecoste and hope to make her last longer? A. Commercial crecoste is commonly a mixture of crecoste, picamar, and light tar oil. The coloriess transparent liquid usually sold by pharmacists is the purified crecoste. The former is the substance used for wood. The wood is impregnated with the creceste by immersing it in the is impregnated with the crocsote by immersing it in the liquid, usually under pressure. It is not usually applied with a brush, as you suggest, and is not sul for inside woodwork.

(25) H. A. C. writes: A diploma on parchment was, as I thought, greatly injured by dropping writing ink near and adjoining the printing on the side of the diploma. Framing would not hide the blots. Not knowing what I was doing I used a strong solution of tartaric acid for the purpose of removing the stain. This only served to change the color of the blots from black to bloe. It was much fainter, however, than before, and appeared to be in the parchment rather than on it, as before. The parchment had shrunker somewhat now after drying, but as the spot was not larger than a silver quarter, it was not noticoable. I now took chloride of lime to remove the blue stain, but this solution served to shrink the parchment where it was wet to a considerable extent. Not having any means of stretching the spot, and not knowing what to use for that purpose, I laid the diploma away as soon as it dried and have never since opened it. Will you tell me how can I get the spot back to its former dimensions? A. You may try the following: Moisten the spot with water, and rub it over gently at first with the white of an egg mixed with a small quantity of freshly propased four paste. Press between biotting paper with a warm fron. A little alum and a trace of oil may be added to the paste if found necessary.

(28) E. V. D. Writes: I have a sun dial (25) H. A. C. writes: A diploma on parch-

nen metal sont is fead superficially rolled with tin.

(26) E. Y. D. writes: I have a sun dial

(16) C. T. F. writes: I observe in your made in Germany for 48° 18′ latitude, and I want to ournal of July 31, p. 69, an article pertaining to the value

not, why? And how much difference will there be at 12 o'clock now? A. We should infer yours to be a horizontal sun dist, and will give correct time only in latitude for which it was made, save when sun in meridian; because the gnomon or style by which the readow is east must be placed parallel with the polar axis of the carth, and the base upon which the shadow is east parallel with the horizon, both or which cannot be done when a change of latitude is made. If the style of your dial is set truly in the meridian of your place, and depressed to correspond with your latitude, it will give you 6 o'clock A.M. and 6 o'clock P.M.. also the exact sun or true time, at noon

MINERALS, ETC.—Specimens have been received from the following correspondents, and

examined, with the results stated: W. N. W.-Galena-lead sulphide, a rich lead ore. It probably carries a little silver-worth assaying.

INDEX OF INVENTIONS

Letters Patent of the United States were Granted in the Week Ending August 17, 1880. AND BACH BEARING THAT DATE.

[Those marked (r) are reissued patents.]

A printed copy of the specification and drawing of any patent in the annexed list, also of any patent issued since 1866, will be furnished from this office for one dollar. In ordering please state the number and date of the patent desired and remit to Munn & Co., 37 Park Row. New York city. We also furnish copies of patents granted prior to 1895; but at increased cost, as the specifications not being printed, must be copied by hand.

Advertising, automatic device for, R.M. Westlake 231,204

Aging liquors, apparatus for, J. H. Thierman 231,877
Air brake for railway trains, J. Hall 201,811
Azie cutting device. L. A. Young 201.387
Bale band tightener, C. T. Christmas 281,273
Baie tng, P. Cohen 231,377
Enling press, P. K. Dederick
Belting, mackine for making rubber, J. D. Joelin. 281,327
Borth, self-leveling ship's, H. A. Darrin 231,264
Blasting charges, primer for, A. Nobel 231,348
Boat detaching apparatus, J. L. Knight 231,179
Boiler furnace, steam, W. H. Harrison, 231,315
Bolt cutter, A. Fisher 281,290
Book holder, W. F. Eppler 281,215
Boot and shoe, waterproof, C. A. Hasign 281.298
Boot, India-rubber, C. A. Ensign 231.294
Bottle stopper, J. Klee 231,200
Bracelet clasp, H. Murray 231,235
Brewers' grains, drier for, F. W. Wiesebrock 231 384
Bridge, triangular truss, C. W. Wheeler 281,383
Buckle, harnoss J. A. Gavitt
Buckle levers, machine for making, L. A. Sprague 231,199
Burring and ginning cylinder, J. K. Proctor 231,357
Button and stud, C. H. Mureford 281,384
Buttons from plastic materials, manufacture of,
P. L. Sylvester
Came for machinery, construction of, J. Brady 281.165
Canal lock and dam, G. W. Parsons (r) 9 345
Canal lock and dam, G. W. Parsons (r)
Cans and other vessels, nozzle for, L. F. Betts 231,144
Cans and other vessels, noszle for, L. F. Betta 231,144 Car brake, S. Rimery
Cans and other vessels, nozzle for, L. F. Betta 231,144 Car brake, S. Rimery
Cans and other vessels, nozzle for, L. F. Betta 231,144 Car brake, S. Elmery 231,294 Car brake, electro-magnetic, J. Cochran 231,276 Car brake mechanism. F. W. Chaffee 231,276
Cans and other ressels, nozzie for, L. F. Betts 23,144 Car brake, 8. Emery
Cans and other ressels, nozzie for, L. F. Betts
Cans and other vessels, nozzie for, L. F. Betta
Can and other ressels, nozzie for, L. F. Betta
Can and other ressels, nozzie for, L. F. Betta
Cans and other ressels, nozzie for, L. F. Betts. 231,144 Car brake, 8. Emery. 231,291 Car brake, electro-magnetic J. Cochran 231,276 Car brake mechanism. F. W. Chaffee. 231,271 Car coupling, J. A. Dickinson 21,276 Car motor, street. J. Lockhart. 231,138 Car roof, J. D. Felthousen. 231,220 Car apring, E. Cliff. 231,200 Carpet strateher, W. O. Hogue 231,147 Carriage curvain fastening, F. A. Neider. 331,345 Carriage curvain fastening, F. A. Neider. 331,345

HISTORY AND PARTICULARS OF DR.
Tanner's Becent & Gay Fast.—By P. H. Vander Weyde,
M.D. Dr. Vander Weyde was one of the scientific experts and watchers who attended throughout the fast,
and made the chemical and microscopical examinations
of the excretions and blood of the patient. The present
interesting and valuable paper contains an account of the
origin of the trial, and the condition and changes noted in
the patient from day to day. The paper is accompanied
with a table of Physiological Observations showing the
alteration in Dr. Tanner's weight, as successive periods,
quantity of water taken and volded, quantities of urea
and phosphates, engraving of the remarkable changes
in the form of the patient's blood corpuscies, as seen in
the microscope, with many other valuable particulars.
Contains in BCENTIFIC AMERICAN SUPPLEMINET. No.
244. Price II cents. To be had at this office and from
il newsdealors.

SECOND-HAND ENGINES,

Mesers. Munn & Co., in connection with the public of the Scientific American, continue to example. nte, and to act as Solicitors of Pate

In this line of business they have bad OVER THIRTY YEARS' EXPERIENCE, and now have usequaled facilities for the Preparation of Patent Drawings, Specifications, and the Prosecution of Applications for Patents in the United States, Canada, and Foreign Countries. Messrs. Munn & Co. also attend to the preparation of Caveata, Registration of Labels, Copyrights for Books, Labels, Reissenes, Assignments, and Reports on Infringements of Patents. All business intrusted to them is done with special care and promptness, on very moderate terms.

We send, free of charge, on application, a pamphlet containing further information about Patents, and how to procure them; directions concerning Labels, Copyrights, Designs, Patents, Appeals, Reissess, Infringements, Assignments, Rejected Cases, Hints on the Sale of Patents, etc.

Foreign Patents.—We also rend, free of charge, a Synopsis of Foreign Patent Laws, showing the cost and method of securing patents in all the principal constries of the world. American inventors should hear in mind that, as a general rule, any invention that is valuable to the patentee, in this country is worth equally as much in England and some other foreign countries. Five patents—embracing Canadian, English, German, French, and Belgian—will secure to an inventor the exclusive monopoly to his discovery among about our ENTENDERD AND FIRTY SPILLIONS of the most intelligent people in the world. The facilities of business and steam communication are such that patents can be obtained abroad by our citizens almost as easily as at home. The expense to apply for an English patent is \$75; German, \$100; French, \$100; Belgian, \$100; Canadian, \$50.

Copies of Patents.—Persons desiring any patent issued from 1836 to November 20, 1866, can be supplied with official copies at reasonable cost, the price depending upon the extent of drawings and length of specifications.

Any patent issued since November 20, 1983, at which time the Patent Office commenced printing the drawings and specifications, may be had by remitting to this office \$1.

A copy of the claims of any patent issued since 1836 will be furnished for \$1.

When ordering copies, please to remit for the same as above, and state name of patentee, title of invention, and date of patent.

A pamphlet containing full directions for obtaining United States patents, sent free. A handsonely bound Reference Book, glit edges, contains 140 pages and many cogravings and tables important to every patentee and mechanic, and is a useful handbook of reference for everybody. Price 25 cents, mailed free.
